The only factor which is liable to perhaps a strong upward movement is that of labor, which is undoubtedly now low. This, however, will probably be counterbalanced by a wider use of labor-saving devices both in mining and in handling the coal. There may therefore be, in times of greater activity, an upward movement in prices; but we do not look for any relative increase.—*Coal.*

AN ELECTRICAL LAUNCH.

A launch propelled by electricity was shown on the Thames on several occasions last year, and attracted a good deal of attention. It was propelled by a screw driven by a Siemens motor and Sellon-Volckmar accumulators. To a certain extent, the experiment was successful. Recently Messrs. Yarrow & Co., of the Isle of Dogs, took the matter up, and, working with the Electrical Power and Storage Company, a very handsome launch has been fitted up, intended for the Vienna Exhibition, with which many experiments have been made. On Tuesday, this little boat made a run from the Temple Pier to Greenwich in thirty-seven minutes, with a moderate tide. Some delay was, moreover, caused by the propeller fouling a basket, an event well known to every one who has had any experience with steam launches on the Thames. The distance is six miles, so that, making allowance for the tide, it may be said that a speed of over seven miles an hour was attained, and full power was not employed save for a portion of the time. On the measured mile, an average speed of over eight miles an hour has been obtained.

The boat is 40 feet long and of good beam. She had twenty-one persons on board, including the steersman and a man to look after the machinery, if such it may be called. The boat is completely unencumbered from end to end, no trace of the propelling mechanism being visible. This consists of eighty cells of Sellon-Volckmar accumulators, of which fourteen are disposed under the seats, seven at each side, and the remainder in the bottom of the boat under the floor. The screw is turned by an A Siemens dynamo commutated as a motor. No gearing is used, the spindle of the armature being coupled directly on to the end of the screw-shaft. The thrust-block is just aft of the dynamo, which is placed under the floor in the stern-sheets. It lies flat and occupies very little space. There are four brushes, two for going ahead, two for going astern, and two small lines going to a becket beside the steersman enable him at a moment's notice, by pulling one or the other, to go ahead or astern; a cylindrical switch beside him enables him to stop or go on at pleasure. This switch is graduated so that the current from forty, sixty, or eighty cells can be used at pleasure. The weight of the whole—batteries and dynamo—is about two tons, or as nearly as possible that of engine, boiler with water, and coal for a steam-engine competent to propel her at the same speed.

This pretty launch is the very perfection of a pleasure-boat; no heat, no smoke, no dust, no steam, no smell of oil, no splashing of pumps. There is no noise of any kind to be heard save the bubbling of the water from the propeller, and the faint hiss caused by the commutator rubbing against the brushes. There is no smell and no "blacks;" and the boat will run for six hours continuously, or about forty-five miles.

During the trip to which we are referring, the current passed through the dynamo was 41·22 ampères from sixty cells, the electro-motive force being 112·5 volts, and $\frac{41{\cdot}22 \times 112{\cdot}5}{746} = 6{\cdot}21$-horse power. The loss by friction, etc., must be very small; for six indicated horse-power could certainly not have propelled the boat at the speed she readily attained. It has long been known that the screw is an extremely wasteful propeller. It may be that further investigations will show that the screw is not so much to blame as the combination of screw and engines. At any rate, the system of electrical propulsion opens up a new field of inquiry, because it renders possible the use of screws of extremely fine pitch revolving at a great speed. The dynamo in Mr. Yarrow's boat makes about 680 revolutions per minute. The propeller is of steel, two-bladed, 19-inch diameter, and 13-inch pitch. There is absolutely no vibration, and very little disturbance of the water in the wake of the boat.

No matter what may be the opinions formed concerning the utility of the electrical propeller for commercial purposes, there can be no doubt that the Electrical Power and Storage Company and its manager, Mr. Collett, and Mr. Yarrow, have together proved that the system is admirably adapted for pleasure purposes. In fact, for such work as that now done by steam launches on the Thames, the electrical system is simply perfection. The expense will be, on the whole, about that of steam; but to those who keep steam launches, expense is a secondary consideration, and it must not be forgotten that a 20-foot electrical launch will afford at least as much accommodation as a 30-foot steam launch. Thus, in Mr. Yarrow's boat, quite 11 feet of the best part of her would be occupied by engines and boilers. As to the supply of storage-cells, that can easily be managed. Many private gentlemen could keep their own engine and dynamo on shore to do the charging, and for the rest it would suffice to establish at certain places on the banks of the river, as at Kingstone, Staines, Maidenhead, etc., depots where, during the summer season, dynamos driven by stationary engines would keep on charging batteries. By calling at any of these stations, enough power for a six hours' run could be obtained either by charging the cells in the boat directly, or by taking the run-down cells out and replacing them with charged cells.

We may add that certain very important improvements have been made in the Sellon-Volckmar accumulator, concerning which we shall have more to say. As now made, they have an E.M.F. of 2·3 volts per cell at starting, and will give five ampère hours per pound of battery—a very admirable result.

A NEW FOUNDRY-PATTERN VARNISH.—A varnish has been patented in Germany for foundry patterns and machinery, which it is claimed—we do not know how justly—dries as soon as put on, gives the patterns a smooth surface, thus insuring an easy slip out of the mold, and which prevents the pattern from warping, shrinking, or swelling, as it is quite impervious to moisture. This varnish is prepared in the following manner: 30 pounds of shellac, 10 pounds of Manila copal, and 10 pounds of Zanzibar copal are placed in a vessel, which is heated externally by steam, and stirred during from four to six hours, after which 150 parts of the finest potato spirit are added, and the whole heated during four hours to 87 degrees C. This liquid is dyed by the addition of orange color, and can then be used for painting the patterns. When used for painting and glazing machinery, it consists of 35 pounds of shellac, 5 pounds of Manila copal, 10 pounds of Zanzibar copal, and 150 pounds of spirit.

A NEW EXPLOSIVE.—Herr Koppel has devised a new explosive substance, which he expects to be less costly than any other, to give out no injurious fumes, and not to be liable to explosion by shock or friction. The following figures give the composition of two kinds, the first of each pair of figures relating to explosives suitable for hard rocks, such as basalt, and the second pair for softer, such as sandstone:

	No. 1.	No. 2.
Saltpeter	35·00	42·00
Soda	19·00	22·00
Sulphur	11·00	12·50
Sawdust	9·50	10·00
Chlorate of potash	9·50	.....
Charcoal	6·00	7·00
Sulphate of soda	4·25	5·00
Prussiate of potash	2·25	.....
Refined sugar	2·25	.....
Picric acid	1·25	1·50
	100·00	100·00

UTILIZATION OF COKE-DUST.—The Chief-Engineer of the Lyons Gas Company, M. Craponne, works up the coke-dust produced at the Perache Gas-Works into briquettes or patent fuel. The coke-dust is first mixed dry with pulverized pitch, and the mixture, raised by an elevator, is subjected to the action of a jet of steam, at from 45 to 75 pounds pressure per square inch, which melts the pitch. The pasty mass is then compressed into briquettes in the Durand and Marais machine, made by Dupuy & Co., of London and Paris. One of the greatest difficulties was found to be the grinding effects of the particles of coke, which acted like emery-powder on the metallic surfaces of the press, and rapidly wore them out. Various parts were accordingly made of chilled cast-iron, from 15 to 20 horse-power being required for driving. At first, the dust was ground, but this has now been found unnecessary. A previous washing is, however, found advisable, which operation reduces the percentage of ash to from 10 to 12 per cent. The briquettes, weighing rather over two pounds each, serve for firing the retort furnaces, being mixed with coke in the proportion of 40 and even 65 per cent of the quantity originally consumed. Some of the briquettes are also sold to iron-masters, for use in the blast-furnace. A ton of this fuel costs rather over 16 francs = 12s. 9d. to produce, or 17 francs = 13s. 9d., including interest on capital and depreciation. The complete works and plant cost 45,000 francs.

INSULATING SUBSTANCES.—M. Eric Gerard, the Belgian telegraphic engineer, professor of applied electricity at the Liége Mining School, has recently published a treatise on the insulating substances used in the various applications of electricity. He remarks that glass may be called the classical insulator, but its fragile and hygrometric properties are to a certain extent inconvenient. Porcelain he considers an excellent substance, its slight porosity being corrected by the process of enameling. He urges the necessity of keeping insulators well cleaned, as dust is capable of impairing their properties. Horn, bone, and ivory are often used in delicate telegraphic appliances; but M. Gerard does not recommend their adoption, as they contain in various proportions organic substances liable to decomposition. Wood has the disadvantage of being hygrometric. He considers ebonite as more suitable for use in instruments of precision than the foregoing substances. Silk is in itself a suitable material; but it is recommended not to employ that substance when dyed in the salts of copper or iron—as is usually the case with green shades—because it thereby acquires a certain amount of conductibility. Gutta-percha and India rubber are well known in connection with the purposes indicated; but M. Gerard gives special prominence to a combination of the latter with a large proportion of sulphur in the form of ebonite. He, however, remarks that it is, after a certain length of time, affected by the oxygen in the air, with which the sulphur unites, the surface of the ebonite becoming greenish and dull. Among various other systems which have been tried for cables, that of Brooks is referred to, which includes an iron tube containing the conductors simply covered with cotton and soaked in petroleum. A Swiss firm of electrical engineers, Messrs. Berthond, Borel & Co., is said to have resolved in the following manner the questions affecting the use of paraffine. The conductors are covered with a wrapping of cotton, and are made into a cable which is plunged into boiling paraffine. The cable subsequently passes through an appliance which gives it successively one layer of resin and two coverings of lead separated by a layer of bitumen. It is said that the electrical properties of such a cable differ but little from those of cables with gutta-percha covering, while its price is notably lower. It is further remarked that for industrial purposes it is not generally necessary to have perfect insulation, but rather to employ such insulating substances as are but little affected by air and heat.

FURNACE, MILL, AND FACTORY.

The Calumet Iron and Steel Company, Chicago, has executed a mortgage for $300,000 on what are known as the J. B. Brown Iron-Works, to A. J. Ives. It is understood to be for the purpose of clearing up outstanding accounts.

S. B. Whitney, of Pottsville, has been appointed General Superintendent of the Lehigh & Wilkes-Barre Coal Company. He is the successor of Charles Parrish, of the Wyoming and Audenreid Division.

The Scranton Steel Company is at present rolling rails which weigh seventy pounds to the yard and 120 feet in length. The four finished rails, after sawing, weigh 2800 pounds. The company, running only single turn, recently made 1008 tons of rails. It has been compelled to double the capacity of its rail-shed and has now four rail-straightening presses in constant use. It is also connecting the mill with the converting department, thereby lengthening the mill about 60 feet and making it 800 feet long.

Representatives from the firm of Edwin P. Allis & Co., of Milwaukee, the successful bidders for the contract for putting up the new pumping machines for the Alleghany water-works, arrived in Pittsburg recently, and engaged in consultation with Superintendent Armstrong about the manner in which to proceed with the work.

A test that proved successful was made recently in Philadelphia of the Ellithorpe patent air-brake and patent air-cushion connected with the elevators in the new building of the Liverpool, London & Globe Insurance Company. The car was weighted with iron rope, and, when disconnected from the hoisting apparatus, fell with great rapidity; but upon the application of the brakes, its descent was instantly checked, the distance traveled from the time of applying the brakes to its actual stoppage being only six inches. In spite of the sudden arrest of the movement of the car, there was no jarring. In testing the air-cushion, the car was allowed to drop from the top story to the bottom, a distance

Digitized by Google

of about 70 feet. As it reached the ground, the compressed air broke the fall, and the car landed easily and safely. Among those present who witnessed the tests were Messrs. Albert Foster and J. E. Wootten, of the Reading Railroad Company; John Price Wetherill, of the Pennsylvania Railroad Company; Mr. McDowell, of the Shenandoah Valley Railroad Company; A. Atwood Smith, B. S. Janney, and B. W. Andrews.

There is a rumor that Stanhope furnace No. 2, Stanhope, N. J., will have to be blown out for repairs.

Rhodes & Bradley, iron merchants, Chicago, obtained a judgment for $82,422 against the Cleveland Rolling-Mill Company, in the United States Circuit Court July 28th. Judge Drummond delivered the decision. In 1879, the Cleveland mill made a contract with Rhodes & Bradley for the delivery of 8000 tons of pig-iron during the next year at $45 per ton. There were 3421 tons delivered on this contract, when, in March, 1880, the price of iron having greatly fallen, notice was served on Rhodes & Bradley that no more iron would be accepted at that price. The iron firm then made tender of the other 4579 tons, which was refused, and began the suit for damages on the contract. The court decided that they were entitled to the difference between the contract price, $45 a ton, and the market price in March, 1880, which was $27 a ton. This amounted to $18 a ton, or $82,422 on the rejected amount. A motion was entered for a new trial, and the amount of the defendants' bond was fixed at $120,000.

On the afternoon of July 24th, Alice Furnace No. 2, at Birmingham, Ala., was blown in. Alice No. 2 is the largest furnace in the State, and there is only one larger in the South—the Victoria furnace, in Virginia. The stack is 75 feet high, with a bosh of 18 feet. It has eight tuyeres and eight iron columns, 21 feet high; Witherow & Gordon's latest improved patent adjustable tuyere stocks; four cooling-plates in the bosh above the tuyeres, with a water-breast below. The bell is lifted and lowered by a special steam-engine with a water-brake attachment. The hoist is Crane Brothers' latest patent; the cast-iron columns used in this elevator, which is 101 feet high, were made in Birmingham by C. P. Williamson. The three stoves, 19 feet in diameter and 76 feet high, are the new Whitwell hot blast in all its completeness, with gas and air-valves and facilities for cleaning. The lining of the stoves is built of Ohio brick. The furnace has a battery of 20 boilers for both furnaces, each 46 inches in diameter and 34 feet long, with two 16-inch flues. The stack is 75 by 18 feet. The two blowing-engines weigh 80 tons each, the weight of the wheels being 16 tons, 16 feet diameter. They were built by the Cuyahoga Forge and Furnace Company, of Cleveland, Ohio. Just in the rear of the furnace plant are 251 coke-ovens, all making coke, with the exception of a few which will be fired this week. Ample storage is provided for stock. The coal storage-room is one of the largest in this region, and has a capacity of 5500 tons. A large number of chutes make a convenience for emptying the coal into larries, which are run upon an hydraulic hoist—the simplest, cheapest, and most durable mode of elevating heavy material in large quantities. It is the expectation of the Alice Company to make 90 tons of iron daily with the new furnace. The average of the old is about 50 tons.

The Cummer Engine Company, Cleveland, has just put in place a 500 horse-power engine for the Brush Electric Light Company, to be used in the manufacture of storage batteries. The company is also sending a 250 horse-power engine to Minneapolis, and has about completed ten large Class B engines, which go to New England. Five of these will be shipped this week. The Cummer Company finds its facilities are not equal to the demands of its trade, and the contemplated addition, 100 by 60 feet, will be erected as soon as possible. This space will be devoted to erecting work, will be swept by three traveling cranes, and will enable the company to carry forward and complete forty engines together. The system of special tools is such that its engines are put together without any lining or facing up, or any special fitting whatever, and its facilities for shipping are so complete that a one-horse outfit is not kept busy half the time, every thing being received and shipped directly to and from the works. In passing through the works, it was noticed that there was a system of electric call-bells and errand-boys, by which a workman could secure any tool he needed without loss of time. It was also noticed that the castings fresh from the molds were unusually smooth and perfect, and the most complete system prevailed in all departments. The Cummer Company has evidently come to stay and to be an aggressive competitor among the manufacturers of high-grade engines.

The Brown Hoisting and Conveying Machine Company, of Cleveland, is fitting a coal storage-house on the Milwaukee dock with three of its hoists. The building is 400 feet by 164, 50 feet high, and will have a capacity to store 35,000 tons of anthracite. The three tramways are suspended from the roof-frame, and adjustable so as to enable the operator of the hoisting apparatus to deposit the coal in any part of the building he desires. The plant will be capable of handling from a vessel and depositing in the building from 1000 to 1200 tons per day, the machines each being operated entirely by one man. The company has shipped and now has in operation an extensive plant for handling coal from canal-boats to storage house at Varrangeville, France. There are also three of its machines in operation on the New York, Pennsylvania & Ohio ore-dock in Cleveland, and another plant is erecting on the dock near the water-works.

The Cleveland (O.) Forge and Iron Company has just placed in its shops a sixty-foot lathe with sixty-inch swing, made by Thomas Shanks & Co., Johnstone, near Glasgow, Scotland.

E. P. Allis & Co., of Milwaukee, Wis., have recently built a pair of blowing-engines for the Edgar Thomson Steel-Works, Pittsburg. The air-cylinders of these engines are 56 by 56 inches, and the steam-cylinders 36 by 56 inches. The aggregate horse-power is 1100.

The government is constructing at the naval arsenal in Washington two six-inch steel rifled guns, and will shortly begin on two ten-inch breech-loading steel rifles. These last will be twenty-seven feet long and forty-two inches wide, weighing each 24 tons. The tubes and jackets are to be imported from England. All of the above-mentioned guns are for use on the new steel cruisers. The ten-inch guns will be very powerful, being able to throw projectiles weighing 500 pounds. The government has never before made any steel guns, but it has a six-inch steel rifled gun, made at the South Boston Steel-Works.

Keel Ridge furnace, at Sharon, Pa., has been blown in.

The new puddling department of Lindsay, McCutcheon & Co.'s mill, at Allegheny, has been shut down.

The puddlers of the Keystone Iron-Works, at Soho, have been put on double turn, to fill an order of 1000 tons of muck-iron for the American Iron-Works.

The Frances Manufacturing Company, of New Britain, Conn., will build another foundry 130 by 40 feet.

The Vesuvius Iron-Works, which have been closed since June 1st, will start in the puddling department to-day and in the nail factory on the 15th.

The Pennsylvania Lead Company, at Mansfield, O., refiner of base bullion, is now using natural gas.

The rolling-mill of the Lake Superior Copper Works Company is running full-time, and finds a ready market for its product, which consists of sheet-copper, copper bottoms, etc. The company has a furnace in connection with its mill, in which it smelts most of the mineral from the Wolverine mine, using the product of other mines only to fill special orders. Two of the furnaces at the smelting-works, Hancock, are rebuilding.

The New London, Conn., Scythe Company has just closed its business for the year past, during which time it manufactured 11,500 dozen scythes, 4000 dozen axes, and 500 dozen hay-knives. The company has been in business since 1835, and did the largest amount of business last year it ever did in one year. On the 21st ult., the company organized as a corporation under the laws of New Hampshire.

Hewes & Phillips's Iron-Works, Newark, N. J., have several very heavy specimens of the machines they build under construction. An immense slotting-machine, weighing over 40 tons, is about completed for the Miller Forge and Iron Company, Pittsburg, Pa. There is a planer of 45 tons weight well under way for the Oregon Iron and Steel Company, Oregon. Several of their standard Allen engines are in various degrees toward completion, one for the Eden Paper Mills being almost ready for shipment. A great deal of care and labor are devoted in these works to giving bearing surfaces accuracy. Ground journals and hardened pins are a regular feature. But all other than bearing surfaces are painted, no polished finish being made for ornament alone.

The Pennsylvania Bolt and Nut Company is fairly started in its new works at Lebanon, Pa. The wareroom is 150 by 50, three stories in hight, with a car-track for the first and second stories. The machine-shop and finishing-room is 120 by 80, the burring-room 60 by 20, and the factory, which contains a 10-inch train of rolls, is 80 by 120. The most improved machinery has been introduced.

The Babcock & Wilcox Company, of New York City, has just issued a circular announcing that Mr. William F. Zimmerman has been appointed manager of its Pittsburg office for the sale of its water-tube boilers. Mr. William Kent, who has had charge of the Pittsburg office during the past year, has been transferred to the general office in New York, as superintendent of the sales department.

The Western Nail Association met August 8th, and decided to order a general resumption of mills for a period of four weeks from next Monday. Trade is light, but the outlook for the fall is encouraging.

Robert Wetherell & Co., of Chester, are now building one of their Corliss engines for the Philadelphia water-works, which will have a horse-power of 1000 and a pumping capacity of four million gallons. This firm is also building an engine for the cotton mills of Matthews & Co., of Selma, Ala. The cylinders of this engine are to be 24 by 48 inches. An engine which it is building for Pope, Cole & Co., of Baltimore, is to have cylinders of 24 by 60 inches dimensions. Messrs. Wetherell & Co. employ 350 men, and turn out an average of six engines per month.

The Cuyahoga Steam-Furnace Company, of Cleveland, has recently built a pair of its blowing-engines for the Franklin, N. Y., Iron-Works, and also a pair for a furnace at Hanging Rock, Ohio.

Malleable iron-works are to be started in Keokuk, Iowa, at an early day. Ground has been purchased and preparations are going forward toward the erection of a foundry, 25 by 30 feet, and finishing-shop, 25 by 40 feet.

The Newburg, Ohio, blast-furnace, which has been idle for several months, has been bought by the Union Rolling-Mill Company. It will be started up some time next week.

The Excelsior Iron-Works, of Chicago, are building a complete copper plant of 20 tons capacity, including engines, boiler, blower, crusher, etc., for the Rocky Mountain Mine-Developing Company. The plant is to be erected at Cañon City, Colorado.

There are three incorporated companies in Warren County, Pa., for the purpose of supplying natural gas for light and heat. Each company has a capital stock of $100,000. These are about to be consolidated into the Warren Light and Heat Company, having a capital stock of $300,000, with Frederick P. Hays, formerly of Pittsburg, as president.

GENERAL MINING NEWS.

ARIZONA.

GILA COUNTY.

OLD DOMINION.—The vapor fuel furnace is now finished. As soon as the petroleum arrives, smelting by that process will begin.

CALIFORNIA.

FRESNO COUNTY.

The prospects of the quartz mining industry are cheering, and quite a fever for prospecting has recently sprung up. Shrewd mining operators are coming in daily, and properties are changing hand.

MONO COUNTY—BODIE DISTRICT.

SPAULDING.—According to the *Free Press*, the personal property of this company, at Bodie, consisting of steam-pumps, pans, shoes, pipe, etc., has been sold by the sheriff to satisfy a Superior Court judgment in favor of A. F. Bryant for about $1800 and costs. Mr. Bryant bought the property for $592.50.

PLUMAS COUNTY.

TAYLOR-PLUMAS.—During many weeks past, the only work done at the mine has been putting down a shaft to reach the ledge near the mill. This end has now been accomplished; the ledge is reached. A good deal of water has been encountered; but still the work is pushed on with vigor.

SAN BERNARDINO COUNTY—CALICO DISTRICT.

GARFIELD.—Work progresses with good results. The lower tunnel is in about seventy feet. The main shaft will be sunk seventy feet farther, to connect with the tunnel. The south winze connects with the lower tunnel. The bullion returns from this mine are very satisfactory.

GOBBLER.—The ore taken out is hauled daily to the Albambra mill. The mine is improving in appearance, and is working in an extension of a rich body of ore.

GOLCONDA.—The claim is carefully prospected and ore has been found in at least a half-dozen places. In about the center of the claim, a shaft has been sunk fifteen feet, from which some good ore has been taken. About seventy-five tons of low-grade ore that will average $60 to the ton are on the dump.

PLUTARCH.—The lessees are working the east end of the claim. Work has been suspended in the shaft, which is down forty feet. The ore in this claim lies in deposits and also in seams.

CANADA.

BELLIVEAU ALBERTITE MINES.—In view of the beginning of boring operations at these mines, the St. John *Telegraph* gives a short sketch of the history of the project. The company owning the mines was organized in 1875 with a capital of $500,000. It owns about four and a half square miles of land in Westmoreland County, extending from the Petitcodiac to the Dorchester River. A shaft 52 feet deep was sunk in 1877 and extended to 267 feet in 1879, and two tunnels afterward were run, one being 326 feet and the other 330 feet long. Small deposits of albertite were found and much inflammable gas. In May, 1879, a discovery of albertite, near the surface, in one of the veins at Taylor Village, induced the manager to prosecute its further development. Shales were struck at a depth of 40 feet from the surface—the vein passing into them. With the view of testing this and the other veins in this locality, a diamond borer was purchased from the government and put into operation in the month of November. At the depth of 100 feet, the borer, at an easterly angle, passed through seventeen inches of albertite, and was continued down through the shale a depth of 335 feet without again striking the vein. A second bore-hole was started a few feet southwesterly from the first. At a perpendicular depth of 170 feet, the drill passed through 49 inches of albertite, the vein being apparently a continuation of that struck at a depth of 160 feet in the first bore-hole—the horizontal distance between the two points being about 15 feet. The second hole again passed through 14 inches of albertite at a depth of 210 feet from the surface, or 80 feet below the 49 inches of albertite; and again, at a depth of 302 feet, passed through two inches, and was continued to a total depth of 325 feet. In view of these interesting developments, and from the fact that the vein extends horizontally along or near the surface a distance of 400 or 500 yards, the manager was instructed to sink a pit near the vein a depth of 200 feet. A shaft was then begun about 20 feet westerly from the 170-foot hole, and sunk to the depth of 165 feet, when a tunnel was projected easterly, to strike, as it was supposed, the

vein of 49 inches. This they did not do; but about the distance from the mouth of the tunnel, and where it was supposed this vein would be, gas made its appearance in such quantities as to make artificial ventilation necessary to render the tunnel fit to work in. This issue of gas was so great that the work was delayed for several weeks, and on three several occasions took fire, and the tunnel had to be flooded to extinguish it. It is now asserted that a mistake was made in the measurement of this shaft, and that it was not as deep down by about 20 feet as the 49-inch vein which they were in search of. The escape of gas from the mouth of the bore-hole, when lighted, burned so brilliantly that it was plainly visible at night for a long distance in the surrounding country, and was found to be so great that, by inserting a pipe securely at the surface, it was brought into the engine-house, not far from the shaft, and utilized, burning night and day, and giving them ample light at all times for five or six months, until their work ceased at that place, and has been ever since escaping through this shaft, now filled with water, as also through the bore-hole, until filled up by some mischievous person, as it now is. Mr. George Botsford, of Fredericton, holds the exclusive right of prospecting over the lands of this company, and it is by him that the diamond borer has been brought to the mines.

ONTARIO.

A number of American mining companies are working mines in Ottawa County. The American Phosphate Mining and Land Company has carried on active operations in the township of Templeton since September, 1882. Preparations are making to begin work on the property of the International Mining and Land Company. The company owns 1700 acres of phosphate lands. The Dominion Phosphate and Union Phosphate Mining and Land companies are carrying on successful operations on their respective properties.

COLORADO.

ARAPAHOE COUNTY.

The consolidation of the Grant Smelting Company and the Omaha Smelting and Refining Company was consummated a month ago; but was not made known to the public until recently. The capital stock is fixed at $2,500,000, and the company is incorporated for one hundred years, dating from the 5th of last month. There will be no changes in the location of the works or the administration of affairs, as the new order of things has been in existence for a month, and the action there announced is taken merely to perfect the record. The ore smelted by the Grant smelter has been refined at the Omaha Company's works for the past three years, and the two have been co-operating that length of time. They are now placed under one management. Sidney Dillon, President of the Union Pacific Railroad, is one of the parties brought into direct interest in Denver's welfare by this transaction, he being one of the stockholders of the Omaha Company. The following gentlemen have been elected directors by the stockholders of the new company: Guy C. Barton, Edward W. Nash, James B. Grant, Edward Eddy, William H. James, Charles Babcock, and J. H. Millard.

CHAFFEE COUNTY.

FREE GOLD.—Negotiations have been pending for the leasing of this company's property, which, if completed, would have put in operation the 25-stamp mill belonging to the company.

WEBER.—This mine, which has lain idle since last season, is to be started up vigorously. Machinery will be erected and shipments of ore will soon begin.

CLEAR CREEK COUNTY.

BARD CREEK.—This company has been organized to develop the Blue Grass lode on Democrat Mountain. The level now running on the vein from the Bard Creek side of Democrat is in over eighty feet, and shows two feet of quartz which assays forty ounces silver.

NEW YORK & COLORADO.—Work at grading for the new fifty-ton stamp-mill of this company, above Empire, is going forward. Twelve men are running three shifts daily on the Big and Little Chief drifts. The former is in 110 feet, the latter 50 feet. The Big Chief crevice at the creek is 100 feet wide, and prospects well in gold. In the breast is good quartz. Twenty thousand dollars have already been paid down toward the mill, and monthly dues thus far have been promptly met.

PAY ROCK.—The concentrator has now been running about six weeks, double *shift, treating forty tons per day, or 1000 tons a month.* Its success mechanically and financially has been demonstrated beyond a doubt. The exact financial results attained are not at this date available; but as part of the ore shipped has gone to the Georgetown mills, and as the July product is at least $5000 above that of June, some notion can be formed of what is accomplishing.

SNOW DRIFT.—In this property, six parties of lessees are at work, and all in good ore, so that leases with thirty-five per cent royalty command a handsome bonus.

HINSDALE COUNTY.

LITTLE PRINCE.—*This mine has been sold to Mr. J. L. Shiek, of Denver, for* $20,000.

VERMONT.—A large body of gray copper with native and wire silver has been opened up in the 2d level. At present, they are stoping and taking out a very fine lot of ore. The tunnel is now in over 90 feet at a depth of 200 feet.

LAKE COUNTY.

The ore-production of the Leadville mines, during July, was only a trifle in excess of the previous month, amounting to probably 35,500 tons, against 31,800 during June.

Among the mines showing a decrease are the following: Silver Cord, 500 tons; Mike & Starr, 200 tons; Nellie S., 600 tons; Catalpa, 200 tons; and several others in smaller amounts, making a total of about 1500 tons.

Among the properties showing increased productions are the following, with their respective increases appended: Henriett, 700 tons; Clontarf, 500 tons; Little Johnny, 100 tons; St. Louis, 100 tons; Colonel Sellers, 300 tons; Adlaide, 500 tons; Crown Point, 200 tons; total, 2400.

EXCELSIOR GOLD AND SILVER MINING COMPANY.—A concentrator is to be erected upon the Susie May lode for the treatment of the heavy body of low-grade ore. The vein discovered recently is opening up well, and the prospects for the future are very encouraging. The property is regarded as one of the best in Mosquito Gulch, and the owners are pushing work. On the completion of the concentrator, the force of miners will be increased.

GONABROD.—An important strike has been made in the sub-lease on this property. The first discovery of ore that was made was in a pocket which was exhausted after 70 tons had been taken out of it. New prospecting was then commenced, and from the shaft, which had been sunk to a depth of 100 feet, a drift was run 95 feet. A 6-foot body of galena ore was opened, and the assays made returned an average of 137 ounces of silver and 50 per cent lead. In the No. 1 shaft, another body of galena ore was exposed that averages about $48 per ton. Shipments will be resumed, and will continue steadily from this time.

IRON SILVER.—The Stone mine, during the past month, shipped about six thousand tons of ore. The product of the Iron Silver group, including the Iron, Stone, and leased mines, for July, exceeds ten thousand tons, or the largest monthly product ever made.

The Lime, Seventy-Six, Rock & Dome, are all working under leases, while many of the dumps are sorted over, and concentrated by hand-jigs.

At the Stone mine, the company is hoisting through No. 2, No. 7, and No. 6, or cage shaft. At the latter, a test was made the other day to ascertain its capacity, and a record of twenty-eight cars an hour for the day secured. This, too, in addition to lowering timbers and performing other work with the engines. The cars hoisted contained on an average about three fourths of a ton of ore each.

The Moyer shaft, situated several hundred feet east of the Stone mine, and started about five months ago, has attained a depth of about 250 feet. The shaft is calculated to encounter the contact in its eastern dip at a depth of three hundred feet.

SILVER CORD.—The work of adjusting the losses sustained by the company at the recent fire has been completed, and preparations are making for replacing and repairing the plant. Examination showed that the large hoisting-engines and rigs were not irreparably damaged, and a force of mechanics will be set to work immediately, making good all injuries. A good deal of the other machinery contained in the building at the time of the fire can also be repaired, and it is expected that a comparatively short time only will elapse before the mine will be properly equipped and in full running order again.

TWIN LAKES HYDRAULIC GOLD MINING SYNDICATE (LIMITED).—This company, which is an English corporation, has purchased for $300,000 the placer ground situated between Granite and Twin lakes. The property embraces the well-known claims in Cash Creek, Young America, and other gulches. The Cash Creek property, formerly owned by the Gaff Mining Company, is the best developed of the group. Just before making the transfer of this property to the newly-organized company, a clean-up was made, yielding eight thousand dollars. The auriferous pay gravel on these claims has a thickness of from twelve to three hundred feet, and has yielded largely in the past. They were first discovered in 1859, and many of them have been worked steadily ever since. All told, there are about nine miles of ditches and flumes, which, together with natural water channels, afford an available water supply equal to twenty thousand miner's inches. The company will take hold of the property immediately, and push its development with all possible haste. Among other work to be commenced at once is the construction of a large water-ditch, five miles in length. The construction of a telephone line from Leadville to the placer-fields, a distance of about twenty miles, is in progress, and also the erection of office and other buildings.

OURAY COUNTY.

AMES.—The smelter is no longer an experiment, but an assured success. In a run of less than four weeks, with ore-furnace, ten car-loads of bullion were produced.

MADISON.—Eight feet of brittle and ruby silver and gray and yellow copper have been uncovered on this claim. Two hundred and fifty sacks have been taken out.

ROSE.—A recent discovery of rich gold and crystal-bearing quartz is reported. The strike is in the main tunnel of the group.

PUEBLO COUNTY.

PUEBLO SMELTING AND REFINING COMPANY.—Two thirds of the employés are out on a strike for increased wages. The prices demanded are as follows: Furnace-men and feeders, $3 per day each; weighers, wheelers, pot-pullers, and calcimer men, $2.50 per day each; roustabouts, $2 per day each. The prices heretofore paid by the company, and which have been in force for the past three years, are: Furnace men and feeders, $2.50 per day each; weighers, wheelers, pot-pullers, and calcimer men, $2 per day each; and roustabouts, $1.75 per day each.

DAKOTA.

CALEDONIA.—For the week ended July 29th, the superintendent reports: Ore produced, 1050 tons. The header on the 400 level is in sixteen feet. The last four feet improved very much in appearance and also in quality of ore. All other parts of the mine are looking the same as usual.

ETTA.—San Francisco parties have purchased this mine for about $50,000. The work of development continues for the present; and as soon as the company has secured control of the property, the mining and reduction of the ore on a large scale will be commenced.

FATHER DE SMET.—The superintendent reports, July 19th: Herewith express company's receipt for bar No. 163, containing 908·9 ounces of gold, the result of run of mill for first half of July. On the 16th inst., I drew for $20,300, which amount was for all expenses incurred during the month of June. The engine in mill is doing better work than at any time for the last five years, and a new one will not be required, as we supposed a year ago. Nearly all the ore-faces are showing a decided improvement in both quantity and quality. We are at present ordering supplies for the coming year from Chicago, among the lot being 600 stamp-shoes, iron, candles, oils, etc. For the week ended August 1st, the report shows: Ore extracted from first, second, and third levels, 3000 tons. Ore milled, 3000 tons. Tramway level rise for month, 25 feet; total, 105 feet finished. Golden Gate east cross-cut advanced 7 feet; for month, 19 feet.

KING SOLOMON.—The Black Hills *Journal* states that the affairs of this company do not seem to be in the best possible condition. The men who have worked on the mine have not been paid, though wages for several months are long past due. Recently a large number of claims were filed against the company.

GEORGIA.

CHICAGO & GEORGIA.—This property, after lying comparatively idle for some time, has passed into the hands of energetic parties, who have added to it, by purchase of adjoining lots, a large amount of valuable mining ground. They have also erected an entire new plant. A new cut has been commenced, which will give access to the veins at a point considerably below the bottom of the old one. The twenty-stamp mill has been started up on ore from the new cut.

IDAHO.

BULLION CONSOLIDATED.—The company is loading on teams for its mines in Little Smoky Mining District a very complete outfit of machinery and supplies, consisting of a steam saw-mill of improved make, with ample power for extra saws, planer, etc. A concentrating-mill of 50 tons capacity, the machinery for which has already arrived and is now loading on teams to be taken from the railroad depot to the company's mine, will be erected at once.

WOOD RIVER REGION.

The Mayflower, Bullion, Jay Gould, and Idahoan have each had concentrating-works placed upon the properties to concentrate the second-class ores which would not pay for shipping. All of these use jiggers with good results, producing concentrates as rich as if not richer than first-class ores. Each of the mines named looks well, as does also the Eureka mine.

At Ketchum, the Philadelphia Company has a fine smelting-plant, two stacks in operation, and two new ones ready to start.

The new twenty-stamp silver mill at the Vienna mine has been in operation some three or four weeks, and is doing fine work. This mill is owned by a company owing and operating the Vienna, Mountain King, and some other mines. The former is turning out very rich ore, but the body is not so large as that of the Mountain King, which is classed as a mammoth mine. The company is working about the mill and mines 125 men. The Solace mine is lying idle from want of water, but expects to start up in a few days, and will be pushed with a good force of men.

Sawtooth is reported dull, with but little life in the camp because some of the properties are tied up, or in the hands of companies not disposed to operate at present.

YANKEE FORK REGION.

A correspondent of the Salt Lake *Tribune* says that Bonanza is the center of the Yankee Fork mining country, where once there was much activity in place mining, and, later, in prospecting for quartz leads and opening them up. With the discoveries and consequent excitement in the Wood River country, this locality became much neglected for a time, and Bonanza and the country around has had but little life the past three years.

Digitized by Google

The Charles Dickens is the best mine in the district. There are 2300 feet of tunneling. The main tunnel is in 950 feet, and a shaft 120 feet connecting the upper with the lower tunnel. The ore is free-milling gold and silver, the vein averaging from 1½ to 6 feet, and runs from the top of the ledge down; 500 tons of first-class ore will be milled the coming month at the Custer mill. Over 300 tons are sacked and ready for shipment, which will average $200 a ton. About $4800 in gold bullion has been shipped this season, the work of the arrastra from low-grade ore. The arrastra works two tons daily. There are 8000 tons of second-class ore on the dump, averaging $50 a ton. Last season, thirty tons of first-class ore were shipped to Salt Lake, averaging $860 per ton. The mine never looked better, some of the ore assaying $4000, some going as high as $25,000 per ton. The only thing needed is a good stamp-mill to work the ores.

The Juliette is the eastern extension of the Charles Dickens, has just started work. The shaft is down twenty feet and the vein five feet wide, the ore averaging from 100 to 400 ounces silver and a percentage of gold.

DAN O'CONNELL.—This mine is situated on Dickens Hill, parallel with the Charles Dickens claim. Several tunnels are run on the vein. The vein is three to five feet. Considerable ore is on the dump.

PILOT.—This is at the west end of Dickens Hill. The vein is from four to five feet; the tunnel is in 46 feet, with the same class of ore as the Dickens.

PARADISE GROUP.—This comprises the following mines: Paradise, Washington, Fair Play, and Passover, owned by John G. Morrison. This group is situated west of the Pilot and is an extension of the Dickens ledge. There is a tunnel in 75 feet on the Washington. The main tunnel in the Paradise is 200 feet, having some very rich ore.

Mr. Morrison is working his placer claim on Jordan Creek, and is getting out some coarse nuggets. He is ground-sluicing and hydraulicking, uncovering the ledge of the Paradise group, where he will be apt to find some rich ore adjacent to the ground where the largest nuggets were found. The placer claim is very rich and paying well.

MONTANA.—This is situated in Yankee Fork Mining District, and is at the head of Jordan Creek, six miles from Bonanza City. It has a shaft down 350 feet; tunnel run in on level 185 feet. The vein in the shaft is eight feet wide. The ore, averaging $150, is free-milling gold and silver, gold predominating. The mine is shipping 350 tons of ore to the General Custer mill, which will be worked by the first of August. Forty tons worked this spring at the mill averaged over $600.

WHALES.—This is situated one mile west of the Montana. The ore croppings are traced for over 800 feet. The vein is from 8 to 15 inches, going from $300 to $2000 per ton. It is looking well and will prove to be a good property.

Two miles north from Bonanza City is a thirty-stamp mill, run by 118 horse-power Harris-Corliss engine; three 54-inch boilers, 16 feet long, 8 pans, and 4 settlers. The General Custer mine and the Unknown are owned by the General Custer Company. The mill was built in 1880, and has been working on General Custer ore continually up to the present, but is now clearing up, and will start working ore from the Unknown. The bullion has averaged over $60,000 monthly; 35 tons of ore were worked every twenty-four hours. The mill employs 32 and the mines 36 men. The mill this season has worked custom ores from the Montana, Charles Dickens, and Badger, and will work ten stamps on Montana and Charles Dickens ore the coming month.

KANSAS.

According to reports, persons engaged in digging a well recently on Governor Dale's farm, five miles northwest of Yates Center, at the depth of twenty feet struck a large vein of silver ore, specimens of which were assayed and found to be very rich. Several shafts are sinking.

MEXICO.

Correspondents of the Mexican *Financier* show that matters are not of a lively nature at Pachuca. The board of directors of the Encino mine, it seems, are having a new survey made of the workings. No doubt before long, this mine will be in full blast once more. The New Progreso hacienda is to start up in a few weeks. It seems so strange, in this enlightened age of improved machinery of all kinds, that a large and powerful company, like the owners of this hacienda, should, instead of putting in all the latest improvements, go back to the ways of the time of the Conde de Regla.

Nothing is doing with the Magdalena mine, owing to some misunderstanding among the stockholders; but work at the next mine to it, the San Nicolás, is pushed. The mine is now down 140 varas. At 10 varas deeper, a cross-cut of from 15 to 20 varas is to be made on to the principal lode. The Corpus Christi mine, which is quite close to the above, goes into the hands of a New York company of which Capt. George Brown, of the New York Board of Marine Underwriters, is president. The San Diego mine is down some 64 varas. There are some very good indications of paying ore.

The Pachuca River Concentrating Company's works are going up as fast as can be expected. The heavy rains that have prevailed here during the past month have been very much against them; but still the early part of August will see them hard at work. Owing to the unusual amount of water in the river of late, they have been unable to extract any quantity of tailings.

The new lode at the Guadalupe mine is turning out much better than was at first thought. Stock of the Anglo-Saxon Copper-Works Company is going up. There was a sale here last week of 20 *bonos* at the rate of between $50 and $60 each. This stock was bought, we believe, for parties in England.

The Real del Monte Company's new hacienda of San Antonio is pushing ahead night and day. The news from Chihuahua indicates a flourishing state of things. The mill, buildings, etc., of the Santa Eulalia Mining Company are nearly completed, and the first shipment of bullion is expected by the end of next month.

A big find of copper is reported east of Santa Rosalia; also a very rich deposit of quicksilver near Huajuquilla. Americans are prospecting both.

Judge Shaw is fitting out in Chihuahua to begin work this rainy season on his Santo Domingo placer. This placer is supposed to be the largest and richest on the continent, containing over 2000 acres.

Final settlements in the sale of the Refugio mine are making in the United States. The ore now runs high, and from 100 to 500 ounces to the ton are worked out.

The Jesus María District is looming up, work being pushed as rapidly as possible. The Tabor-Weston men expect to ship bullion shortly. Mr. Stanton, of the Santa Edowigis Mining Company, has on the way a smelter, concentrator, 25-stamp crusher, saw-mill, etc, and hopes to be running by the end of August. The ore runs from 40 to 1000 ounces. The Knotts Silver Mining Company, of Parral, has abandoned the idea of pumping out the old Prieta mine and is sinking a new shaft. The mill is turning out silver regularly every week.

The Aguilarania mine is down 278 feet, and the men have already cross-cut some 40 feet, and expect to have to go 40 feet more before striking the vein. They are sinking as fast as possible.

The Dry Mountain Company's work is still shut down, awaiting the settlement of the company's financial troubles. Formal work has been stopped on the Veta Grande, awaiting hoisting machinery. The Philadelphia Syndicate has started work on its Gigas mine. The ore is low-grade, but in large bodies.

Mr. V. A. Cowdery, of New York, has begun sinking a new shaft on the Southern extension of the Jesus María mine. The Jesus María seems to improve every day. A rich body of ore 12 feet wide has been opened up lately.

The Stirling Company has its pans in place, and expects to begin running immediately. It is turning out large bodies of ore from its Pedrasania mine. The Ward Mining and Milling Company, of Parral, has begun work on the foundations of its Stetefeldt furnace. The engine and pans are already in place, and there was a trial run on some old tailings, which worked well. The old mill still continues to turn out bullion.

The Tecolotio mine has been sold, and the new company is clearing the ground and getting in the foundation of its mill to smelt 100 tons of ore a day. The mine can produce twice that amount of ore. Every thing is in readiness to put in the new pumping and hoisting machinery at the San Francisco del Oro.

The Providencia Mining Company, of Philadelphia, has nearly completed the smelting hacienda on the river Listin; but before the end of the rainy season they do not expect to do any more than make a trial run.

Charles H. Ward, in the Carmen District, has nearly all his machinery for a forty-stamp mill on the ground, but, until after the rains, will continue to use the old patio process. The mine is looking well, showing very good ore, but inclined to be streaky.

Gen. H. P. Bee has resigned from the Washington Jude Mining Company and Mr. Frank B. Hein, of Silver Cliff, Colorado, is now in charge. The mill is not running, and the company is only working its San Antonio mine, which looks very fair, having an 18-inch streak of good galena ore, averaging about 90 ounces to the ton. The Jude Mining Company, of Washington, has also begun to open up its mines in a small way. Good reports come from Guanacevi, though as yet but little work has been done, and from Mapimi, where the smelters are a success.

The Sierra Mojada District is not doing as well as it should, on account of the cost of the reduction, no stone in the country standing more than one week in the furnaces. The district is, however, shipping three car-loads a week of base bullion to England.

MICHIGAN.

NONESUCH.—This copper mine has been closed to await further developments in the way of additional funds, the company refusing to advance further amounts. About $400,000 have been expended on this property the past year in machinery, buildings, etc, and it has one of the finest plants in the country. Twelve thousand cords of wood, 1800 barrels of salt, and several hundred barrels of copperas are in stock.

MONTANA.

SUMMIT VALLEY DISTRICT.

ANACONDA.—Eexcavating for the new smelter building began July 23d.

CLARK'S FRACTION.—Recent developments show favorable prospects. The sill-floor of the 80-foot level is now 40 feet wide, showing a breast of ore the entire width which assays 50 and 60 ounces. On this level, the workmen are putting in square sets forty feet wide. The Fraction is on the Rainbow lode, between the Alice and the Magna Charta. The peculiarity of the lode is that, wherever it has been developed, it has been found to be from 50 to 60 feet wide, having a well-defined north, south, and center vein of pay, separated from each other by porphyry and barren vein-matter. The Fraction is situated upon lower ground than the Alice, Moulton, or Magna Charta, and just west of a gulch which seems to have changed, at that point, the formation of the great lode, so that it bears ore of a high grade clear across the lode, in place of the porphyry and barren vein-matter which characterize the lode elsewhere.

MAGNA CHARTA.—At this mine, the principal work just now is the sinking of the 3-compartment shaft to the 600. Sinking will be vigorously prosecuted, and the north, south, and center veins of the Rainbow lode, which carry the same characteristics in this mine as in the Alice and Moulton, will be thoroughly developed by cross-cuts, drifts, and levels. The stopes of the upper levels are looking well and producing their usual output of ore.

MOULTON.—The winze from the 300 southwest drift is looking well; but extraction from this valuable ore-body has been temporarily suspended pending the running of a connection with the surface, which has become necessary for purposes of ventilation. Ore is stoped from the 200 west drift, where the ledge of high-grade is looming up bigger than ever, having widened to 6 and 7 feet of solid pay-ore of high grade, clear across the face.

POLLACK.—The Clark Brothers, of Walkerville, have leased this mine, situated northeast of the Alice. They will put a force of men at work, and thoroughly develop the property.

NEVADA.

The custom of working mines on tribute, says the *Sentinel*, is growing more and more general in the Eureka District. Chances that were formerly taken by mining companies are now largely taken by individual miners who try their fortunes in "pitches." At present, the tributers in the Alexandria, Hamburg, Phœnix, and other mines that we could mention are making more than $4 a day. In the first-named mine, the tributers for July made only a little less than $200 each.

It will be learned with pleasure, particularly to Gold Hill, says a local paper, that, by turning the water from the ranches up toward the head of the Carson River, sufficient water will be obtained to run the mills to their full capacity. Thus all the miners may resume work and all go on as usual in the Yellow Jacket, Kentuck, Crown Point, Belcher, and all the other mines.

ALTA.—At the mine, they are getting things in shape for pumping out the lower levels. This will require three or four months. The water now stands at the 1100 level, and between that and the 2150—the lowest level—there are at points some very long drifts; besides, the ground is about as thoroughly saturated with water as when the mine was first opened. The short distance that it is required to pump the water will, however, greatly expedite the work. Also, the strain on the apparatus will be greatly reduced, as all the pumps from the 1080 level to the surface will be taken out. This will make the lower pumps run light.

MARTIN WHITE.—An official letter says that there is but little change to note in the condition of the mine or the quality of the ore. The cave drift is looking well; the drift to the south is in about 15 feet, and the ore is about as wide as the drift and extending above and below. Much of this ore is of good quality, 50 or 60 ounces. A drift to the north has been started, showing good ore on that side also. The stope opened on the M. P. level is looking fairly, but it will take several days yet to prove it. The rock is rather hard at present for good ore, still it looks well and generally assays well. Stope No. 2 is in good ore; No. 1 is not at present.

MEXICAN.—The work of repairing the Central tunnel and the old Mexican shaft will now soon be completed, when a great amount of low-grade ore may be cheaply extracted from the old upper works.

SILVER STATE CONSOLIDATED.—The contractors in this mine are making good progress. The company is drifting toward the croppings from the end of the tunnel. Some low-grade ore has been struck, and the indications are better now than they have been heretofore. In working toward the croppings, many changes in the ground are taking place.

NEW HAMPSHIRE.

CRANE.—Work has been resumed at this mine.

MASCOT.—The company has received from the Cunningham Iron-Works a seventy horse-power engine and boiler for its new concentrating-works.

NEW MEXICO.

OLD MAN.—At a meeting of the stockholders held recently, the following officers were elected: President, J. W. Fleming; Vice-President, C. P. Crawford; Treasurer, R. B. Higbee; Secretary, John A Moses. The Board of Directors consists of J. W. Fleming, C. P. Crawford, R. B. Higbee, P. June, and C. Osborne.

NEW YORK.

A large deposit of mica has been found on the farm of Wilson Brown, at Chester, Warren County. About one thousand pounds have already been taken out, and tests prove the mica to equal in quality that of North Carolina.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Aug. 10.

There is nothing of special interest to note in the mining market. A large business has been done in the fancies, but the high-priced stocks remain very quiet. Prices have been a little better, as a rule, but have not gained materially. Horn-Silver has been the exception, for some reason selling quite weak to-day. The Comstocks have been fairly dealt in, but have been very irregular in price, owing to several assessments being levied. We give a summary of the market below. The total number of sales aggregates 193,655 shares, as against 190,513 last week.

The Comstock shares have been moderately dealt in at irregular prices. California was quiet and irregular, selling from 37@44@40c. Consolidated Virginia records a small business, and has been weak, selling from 67@59c., assessment paid, and from 33@43c., assessment unpaid. Sierra Nevada has just levied an assessment of one dollar per share. It has been weak in consequence, and has sold from $5.75@$4.90. Union Consolidated has been quiet and irregular, selling at $6.50@$6.25, assessment paid, and from $4.90@$5.75@$5, assessment unpaid. Ophir was quiet and steady, selling from $4.25@$4. Consolidated Imperial, with a small business, was steady at 8@7c. Best & Belcher sold at $4.50. Sutro Tunnel was quiet and steady, selling from 23@20c.

The Leadville stocks were also moderately dealt in and were steady. Amie was quiet and steady, selling from 15@18@17c. Chrysolite developed a little weakness, under a small business, and sold from $1.25 @$1.10. Dunkin was quiet and steady at 24@20c. Iron Silver was strong, selling from $3.05@$3.15, the sales amounting to 650 shares. Leadville declined from 45@30c.; the dealings were small. Little Chief was a little weak at 43@39c., and Little Pittsburg was quiet and steady at 65c. Climax had a small business and was strong, selling from 6@10c.

The Bodie stocks were very quiet and were weak. Bodie, under a fresh assessment of fifty cents a share, was weak, selling from 50@35c. Standard showed a little weakness, with a small business, declining from $6.63@$6. Bulwer was quiet at 75c.

The Tuscarora stocks have been almost neglected. Argenta sold at 25c. Belle Isle was quiet and steady at 35@31c. Navajo sold at $3.10, with a business of 200 shares. North Belle Isle sold at 35c. Elko Consolidated records a small business at steady prices, selling from 16@15c.

In the miscellaneous list, Alice has been quiet and steady, selling from $2.30@$2.40. Bassick sold at $9.50. Eureka Consolidated was quiet and steady at $5.50. Gold Stripe sold at 7c., and Green Mountain was steady at 74c. Horn-Silver records a small business and has been weak, it sold from $7.75@$6.63. Robinson has been quiet and steady, selling from 66@76@74c. Sierra Grande was moderately dealt in at stronger prices; it sold from 88c.@$1. Stormont was quiet and steady at 35@34c.

Alta-Montana sold at 5c. with a small business. Barcelona has turned up as a very active stock this week. The dealings foot up 32,500 shares, selling from 46@44c. Caledonia was very quiet at $1. Central Arizona was quiet and steady at 15@17c. Decatur records a small business at steady prices, selling at 3@4c. Eastern Oregon has been actively dealt in, and has been strong; it sold from 85@ 87c. Harlem has been quiet and steady at $1.30@$1.35. Oriental & Miller had a small business at steady prices, selling from 13@15c. Rappahannock was quiet at 6c. Red Elephant records a fair business and was steady, selling from 7c@6c. Sonora Consolidated has been very active and hasgained a little strength; it sold from 24@30@29c. South Hite was quiet and steady at 4c.

MEETINGS.

South Silver King Mining Company, No. 154 Nassau street, New York City. A special meeting of stockholders, for the purpose of considering and taking action upon the subjects of bonding the mine, collecting installments in arrears, and such other necessary business connected therewith as shall secure the financial success of the company, together with the entire affairs of the company. August 17th, at one o'clock P.M.

DIVIDENDS.

The Castle Creek Mining Company, of Idaho, announces its regular monthly dividend of three per cent, payable on the 16th inst.

The Holyoke Mining Company, of Idaho, has declared a dividend (No. 11) of two per cent on the capital stock, payable August 18th.

The Jocuistita Mining Company, of Mexico, has declared a quarterly dividend of fifty thousand dollars—fifty cents per share—payable August 31st.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows on the petroleum market:

There was on Saturday last a strong market, the price being sharply advanced to $1.09 from $1.07. On Monday morning, while the fever was on, the opening was at $1.10, which was one cent above Saturday's closing; and during the day, the market was bid up to $1.13. This sharp advance appeared to be chiefly due to the organized action of the Standard or some bull clique to force the shorts to cover and induce public buying. The market broke back to-day and sold as low as $1.08⅛, closing, however, at $1.09⅛.

A very important well is expected on Saturday or Monday. It is Porcupine No. 9, situated in Balltown District, 400 feet north of the developed territory; and as it proves good or poor, the market is liable to be influenced. A new well near old territory on the Brady tract tapped the sand yesterday, and is showing for a good well, but is not yet fully opened. It is said that it opens some new territory. During the past week, Grandin No. 3, an old well that had almost ceased flowing, was torpedoed, and yielded 525 barrels during the first twenty-four hours.

The "runs" of oil to the Pipe Line Company from August 1st to 7th inclusive, are about 35,000 barrels ess than the deliveries; but the last seven days of July showed the reverse, consequently no reliance can be placed on statistics based on only a few days' figures. The demand for refined is light, but, simultaneously with the advance in crudeon Monday, it was marked up ⅛c. per gallon, and, in the absence of any demand, there seemed to be no good reason for it, unless it was designed to influence the price of crude. At this writing, refined oil is ⅛c. lower and crude oil is strong.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Aug. 4.....	$1.07¾	$1.09	$1.07⅛	$1.09	2,326,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, Aug. 9.

Since our last report, the market has been fairly active, and in the early dealings a good degree of firmness was manifested in the leading copper stocks, due mainly to the fact that ingot copper was a fraction higher, and the demand more active. Sales of Calumet & Hecla were made at $250, against $246 the week before, but, owing to disturbances in the general market, as well as lack of buying orders, the price was not maintained, and later sales were made at $245, with the stock now offered at that price. Quincy holds its own well, and sales were made at $46¼@$46, an advance of $½@$¾ over last week. The July product of this mine was 300 tons, a gain of 75 tons over last year; and as the expenses were reduced some $10,000, the result, notwithstanding the lower price of copper, will compare favorably with last year's work. The mine has shipped about 1450 tons of refined copper since the opening of navigation. Osceola was heavy, and, under pressure to sell, the stock was forced down from $21@$19½. Franklin was also inclined to be weak, and on small sale declined from $10@$9. There are no large amounts pressed for sale, and it is not offered at less than $10. Pewabic sold at $8. Huron, at $1⅝.

In silver stocks, with the exception of Catalpa, there has been but little doing. Catalpa was freely pressed on the market, and declined from 47½@35c., with sales of about 7000 shares at these figures. In the later dealings there was a slight reaction, and small lots were sold at 45@42½c., closing at 40c. bid. The reports from the mine are not of a very encouraging nature. Crescent sold at 20c., against 25c. (July 13th). Bonanza Development seems to have lost its old-time activity, and transactions are light. Sales at $1¾@ $1½, against $1⅞, July 26th. Harshaw sold at 50c. Sullivan, at 62½@56¼c. Silver Islet declined from $5@$4.

At the Mining Board, Bowman Silver and Massachusetts & New Mexico are the principal stocks dealt in. The former is steady at 16@17c., while the latter, under favorable advices from the mine, has advanced from 3@5c., and is in good demand. The bonds are selling at $11@$12, and would seem to be a good purchase at these figures.

3. P.M.—There was no change in the market this afternoon. Quincy sold at $46, and same price was bid for it. Catalpa, 37½c. bid, 42½c. asked.

BULLION MARKET.

NEW YORK, Friday Evening, Aug. 10.

The market abroad and here the past week has been without any indications worthy of notice.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended August 10th, as compiled from various sources, amounted to $250,000 as against $194,000, reported for the previous week. The receipts from January 1st, 1883, to date are $6,987,974.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended August 4th	$314,080
Corresponding week last year	1,589,025
Since January 1st, 1883	7,887,064
Corresponding period last year	42,160,213

Imports.

Week ended August 4th	$143,688
Corresponding week last year	133,095
Since January 1st, 1883	7,697,919
Corresponding period last year	2,228,872

Foreign Bank Statements.—The governors of the Bank of England, at their weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank lost £88,000 bullion; but the proportion of its reserve to its liabilities was raised from 44⅝ to 45⅜ per cent, against 36 5-16 per cent at this date last year. August 9th, the bank gained £40,000 bullion on balance. The weekly statement of the Bank

Digitized by Google

of France shows losses of 20,000 francs gold and 250,000 francs silver.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date, from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

METALS.

NEW YORK, Friday Evening, Aug. 10.

Copper.—The situation has not materially changed, though the number of those who predict a good future for the metal is growing. We print elsewhere a letter from a correspondent, who has exceptional facilities for gathering reliable data, which will be accepted on the whole as encouraging evidence. Little has been done during the week. It is stated by some manufacturers that they have no difficulty in getting Lake copper at 15c. We can not hear of any available lower than 15½c., while the bulk is not procurable at less than 15¼c. We understand that 15c. has been offered for round lots for export, without, however, bringing out any sellers. Other brands are quoted 14¼@14½c., and bids have been made for 500,000 pounds at 14c. Refiners on this side are getting much less material than formerly, and the quantities of outside copper on the market are much smaller.

In England, Chili Bars are still well supported, being cabled £63 10s.; but Best Selected, which is free from speculative influences, is quoted lower, £67 10s., a sign which, it can not be denied, is not encouraging.

Tin.—Considerable business has been done during the week, 300 tons changing hands at lower prices, precipitated by the arrival this week by steamers of about 325 tons of Straits and 50 tons of Banca tin. Quotations for spot cash large lines Straits are now 21@21⅛c., while in jobbing lots the metal brings for Straits 21¼@21⅜c.; Lamb & Flag, 21⅝c.; Malaca, 21¼c.; and Banca, 22¼c. London cables to-day £93 10s.

Lead.—The market has been very dull, and there have been only a few sales of Common lead at 4·30@4·25c. As yet, the latter figure is not the one generally ruling; but the weakness displayed, notably in St. Louis, where lead has been offered at 3·90c., will probably carry our market to the lower level at an early date. There is very little confidence in the future of the market in metal circles, and the opinion is frequently expressed that, unless a strong demand comes to the rescue of the market, it will fall off to 4c. gradually. Buyers are very cautious, while production is going on at a steady pace.

Messrs. Everett & Post, of Chicago, wire us as follows to-day:

There have been no changes whatever in our market. Little business is doing, as the demand is only from hand to mouth. On the other hand, offerings are very moderate. Prices are nominally 4·05c. for Common and Refined.

Spelter.—The market is dull and lifeless at the range of 4⅝@4⅝c. for ordinary Western. Silesian has sold at 5c. during the week, less than the cost of importation.

Antimony.—There is no change to note.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Aug. 10.

Mr. Edward J. Shriver, Secretary of the New York Metal Exchange, publishes the following returns from 126 furnaces:

STOCKS AND PRODUCTION.	No. 1.	No. 2.	Forge and lower grades.	Grade not specified.	Total.
Stocks July 1st..	13,217	21,929	46,066	17,846	99,058
" August 1st	12,178	17,342	43,970	18,250	91,740
Product'n in July	17,953	6,769	23,149	13,834	61,705

American Pig.—The dullness which we had occasion to note in our last issue has continued, and the outlook is at present certainly not as bright as many would have the public believe. The pig-iron trade is not one to adapt itself rapidly to any changes, and while the known measures taken during the first part of the year have done much toward preventing a very serious overproduction, and have brought about a healthier state of affairs, they have not effected a cure. While No. 1 is certainly not in over-supply and is firmly held, other grades are available in full quantity, and in some cases can only be moved by making concessions. We continue to quote $22@$23.50 for standard to choice No. 1, ordinary brands being obtainable at a concession of 50c.; $19.50@$20.50 for ordinary to choice No. 2; and $18@$20 for inferior to choice Gray Forge. Bessemer Pig is dull at $20.50@$21 at tidewater. Spiegeleisen has sold in considerable quantities, the higher grades at $30.50, and the lower at $25.75@$26.

The week has been an exceedingly quiet one at the Exchange, the only transaction being the sale of 200 tons of No. 1, December delivery, at $22.

Scotch Pig.—Business during the week has been fair at about our quotations. Arrivals are heavier this week, aggregating 2700 tons, and freights are cabled easier, 6s. from Glasgow.

We quote ex ship: Coltness, $23.75@24; Langloan, $23.75@24; Summerlee, $23; Dalmellington, $21@$21.50; and Eglinton, $20.50@$21.

At the Exchange, the following higher cable quotations were received: Coltness, 61s.; Langloan, 60s. Summerlee, 57s.; Gartsherrie, 57s.; Glengarnock, at Ardrossan, 55s. 6d.; and Eglinton, at Ardrossan, 49s. Warrants to-day were 47s. 3d.

Rails.—Business is restricted to small parcels for early delivery, which can not be placed at much lower figures than $38.25@$38.50. There is very little doing in winter delivery, chiefly because makers insist on $38 at mill, which buyers consider too high. There are many inquiries for such delivery, but makers, from being full of work for some time to come, are still indifferent.

Old Rails.—A firmer tone prevails and there have been sales during the week aggregating from 4000 to 5000 tons, all Ts, which are now quoted $21.75@$22.50.

Scrap.—Scrap is dull at $22.50@23 ex ship.

Philadelphia. Aug. 9.

Small transactions have characterized the Eastern Pennsylvania iron trade during the past week, with an improving inquiry for heavy fall deliveries. The users of standard and special brands are in the market this week, to ascertain prices for September and October, and in some cases have submitted orders for ninety days' requirements. Opinions differ as to the probable course of trade between now and the end of the year. Should a large consumptive demand arise, prices will certainly improve for all kinds of iron of good brands. The furnaces out of blast will, for the most part, remain out, for the double reason of low prices and uncertain future demand. Stocks of good grades are low in buyers' hands, and $23.50 was paid this week for a few hundred tons of special for early delivery. Standards are selling in small lots all the way from $22 to $23, with offers in hand at $21.50 and $21.75. Some inferior No. 1 sold at $21, but it was no better than No. 2. Standard No. 2 commands $20.50 in some cases, but sales have been made down as low as $19. Inquiries for Forge are more active than for Foundry, because of the probable resumption of the rolling-mills in September. Prices range from $17@$19.50 at furnace; the latter being for two or three special and very scarce brands. Average prices are $18, though more or less iron has been sold this week below that price; but nothing of a desirable character can be secured below $17.50. The representatives of companies hold to their confident belief in regard to the future of the market; but with the downward tendency in finished iron, consumers will have no margin to pay more than current prices. It was thought that Bessemer iron in large quantities would be sold this week; but up to present writing, sales have not been closed, though, in all probability, large transactions will be concluded before Saturday night. Prices are $21@$21.50 asked, with $20@$20.50 offered, according to size of lot. A number of small transactions in Scotch iron were closed this week.

Muck Bars are selling at $33.50@$34.50, according to quality.

Merchant Iron is weakening, and quotations run from 2·10@2·20c. The intimations thrown out as to Western competition are realized, and agents from Western mills are flying up and down the country, offering iron at prices with which Eastern men will find it hard to compete. Sales have been made below 2c. here. Common iron, 1·75@1·90c. The mills are not working full-time, and will not for three or four weeks. Meanwhile, manufacturers are endeavoring to secure orders for fall delivery.

An active demand, in a small way, has been maintained for Plate and Tank, all the week, with prices as heretofore quoted. Nothing has been closed in large lots, although negotiations are pending. The requirements will be large, as is indicated by inquiries, and the known needs of several large consumers in this locality.

A very satisfactory condition of things is to be reported in the structural iron establishments, and orders for large lots are of very frequent occurrence for early delivery. Angles are 2·40c.; Tees, 3·20c; Beams and Channels, 3·50c. Some of the sales recently made were at concessions from these prices.

Steel Rails.—The companies continue to do a very satisfactory business, but it is mainly in small orders; 5000 and 10,000-ton lots are heard of, and prices range from $38@$39.

Spiegeleisen is selling in 1000-ton lots at $30.50.

Skelp Iron is 2·10c., in 1000-ton lots.

Sheet-Iron is active for light and galvanized at card rates.

Old Rails can scarcely be quoted, as there are no stocks, and buyers decline to pay asking prices; $24 would be paid for Double-Head rails.

Scrap continues rather quiet, and railroad scrap

and selected yard are not in sufficient abundance to induce holders to shade prices to meet buyers' views.

Pittsburg. Aug. 9.

Manufacturers, brokers, and representatives of furnace companies in this county and outside of it are unanimous in reporting an improving feeling and demand for both crude and finished iron; but they are not asking higher prices for any of their products. Order-books are lean, buyers are comparatively short of material, and, as a rule, can not be induced to purchase as freely as stiff prices demand. Manufacturers, however, are confident that, in a very short time, the requirements will drive buyers into market, and in view of this, are not making large concessions. Prices have reached their lowest limits. A few large sales of neutral mill iron were made at $17; best sales, $18. Red-Short iron in 500-ton lots is moving at $18@$18.50. Native Ore Foundry, $19.50. Lake Ore Foundry, $21.50@$22. Car-Wheel Charcoal iron, $30@$33. Bessemer iron sells in small lots at $21.50, but large buyers refuse to pay more than $20.50. Cash offers secure concessions from asking prices. A few thousand tons of Muck Bars have sold during the week at $34@$35. Manufactured iron is in better demand at 1·90c.; small lots, 2c. Several shipments have been made Eastward. Three more mills will start up. Some few have started from single to double turn. Nails are strong and steady at $2.90 in lots of 250 kegs and upward. Inquiries are in hand for 1000-keg lots, and offers are 15 cents less. Factories will start up next week. Stocks are sufficiently large to meet requirements. Makers think they can hold prices where they are. Large building operations are coming to light. Discounts on wrought pipes are 75 per cent; tubes, 60. Oil-well Casing, 45c. per foot; Tubing, 14@15c. The demand is active. All kinds of merchant steel are in moderate request. Prices are unchanged. Manufacturers could meet a much heavier demand. Sales of Steel Rails in small lots have been made at $38.50. Buyers of large lots will hold back. Steel Billets are quoted at $38. Spikes, 2·60c. Nuts and Bolts, 3·20c. Old Rails are quoted at $23.50; $23 offered. Old Car-Wheels, $19.50@$20. Railroad Scrap, $23 per net ton.

A general strike is threatened in the Connellsville coke region. The miners have just been organized. The McKeesport & Youghiogheny Company is putting on sixty-ton mogul engines.

A railroad eighty-five miles long will be built to the Cheat River, to bring ore into Western Pennsylvania.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Aug. 10.

Anthracite.

There are no symptoms whatever of an improvement in the anthracite coal trade; on the contrary, in several quarters we hear complaints of greater dullness, and reports of low prices are growing more numerous, because there are many who must force sales to take care of the larger amount of coal coming to them. Shippers are still engaged in placing coal bought at June prices; but soon the majority of them will have caught up. There has been some talk of putting up prices the middle of the present month; but to all appearances, the scare is now reserved for the first of next month, when probably all interests may be united to create higher nominal figures, so that those announced a month ago may be actually approximately realized. It is likely that there will be a good deal of buying then. From other quarters, the reports are fairly encouraging.

Bituminous.

Rumors of low prices continue numerous, Clearfield coal having sold to steamers as low as $3.50, a figure which, under special circumstances, may be closely approached by other buyers.

STATISTICS OF COAL PRODUCTION.

The Transportation of Coke over the Pennsylvania Railroad for the week ended August 4th, and year from January 1st:

Tons of 2000 lbs.	Week.	Year.
Penn. RR. (Alleghany Region)	770	52,753

Horsford's Acid Phosphate
As a Refrigerant Drink in Fevers.

DR. C. H. S. DAVIS, Meriden, Conn., says: "I have used it as a pleasant and cooling drink in fevers, and have been very much pleased with it."

DIVIDENDS.

HORN-SILVER MINING COMPANY, Office, 44 Wall Street,
NEW YORK, July 31, 1883.
DIVIDEND NO. 10.
QUARTERLY DIVIDEND of $300,000 has been this day declared, being three per cent on the capital stock, payable to stockholders of record on the 15th day of August next, at the office of the company. Transfer-books will close on August 8th, and reopen August 16th.
W. S. HOYT, Secretary.

SAN FRANCISCO, Aug. 4, 1883.
THE BODIE CONSOLIDATED MINING CO. this day levied assessment No. 3 of 50 cents per share, delinquent September 10th. Sale day, October 10th. Same may be paid at the office of Laidlaw & Co., 14 Wall Street. GEO. W. SESSIONS, Secretary.

OFFICE OF THE JOCUISTITA MINING COMPANY, MILLS BUILDING, 15 BROAD STREET, NEW YORK, Aug. 8, 1883.
DIVIDEND NO. 9.
The Jocuistita Company has this day declared a quarterly dividend of FIFTY THOUSAND DOLLARS, being fifty cents (50c.) per share, payable at the office of Lounsbery & Haggin, Mills Building, No. 15 Broad street, on the 31st inst.
Transfer-books close on the 25th inst.
R. P. LOUNSBERY, President.

SPECIAL NOTICES.

AGENT WANTED.—IN AMERICA FOR the introduction of a new patented Cupola Furnace, in which a brilliant, soft, and tenacious cast-iron can be produced out of crude iron of inferior quality by adding shavings of malleable iron or steel. Address offers to DIRKS & COMP.,
Eisengiesserei in Leer, Hanover (Germany).

WANTED.—A POSITION AS MINING Engineer or Metallurgist, by a graduate of Lehigh University, with several years' practical experience. Can furnish good references from former employers, as to ability and character. Address,
B. F. HALDEMAN, Bethlehem, Pa.

G. E. RANDOLPH & CO.,
CENTRAL CITY, COLORADO,
GENERAL AGENTS FOR NON-RESIDENT OWNERS OF ACTIVE OR IDLE MINES.
Correspondence Solicited.

STEAM PUMPS.
FOR SALE.—A large number of Steam-Pumps of all makes, and ranging in size from small tank or boiler feeds up to very heavy service machines.
While the stock lasts, good bargains are open for Miners, Water-Works, Rolling-Mills, Furnaces, or any one needing to move fluids by steam. Call upon or address
JOHN A. HINCKLEY, Purchasing Agent of
THE UNITED PIPE LINES, OIL CITY, PA.

SMELTING - WORKS FOR SALE
The smelting-works, with a capacity of from 60 to 80 tons per day, situated at Socorro, New Mexico, upon a switch of the A. T. & S. F. Railroad.
These works are entirely new, and are equipped with all the most modern improvements. For sale for lack of capital to run them. For further information address
WILLIAM H. RENAUD,
Care John J. Adams & Co., New Orleans, La.
Or WM. VANSLOOTEN, 683 Broadway, New York.

GREAT MAP OF THE WYOMING VALLEY.
This, the most elaborate and accurate topographical map ever made in this country, outside of the Coast Survey, covers an area of TWO HUNDRED SQUARE MILES, and the work upon it cost over $12,000. It represents a coal-field which produced in 1874 over 10,000,000 tons of Anthracite. The Map was constructed altogether from original surveys. Every Road, Colliery, Building, or land or property line existing at the time is accurately located. The surface configuration is shown by CONTOUR LINES TEN FEET APART, VERTICALLY; and the elevation of every point above sea-level is given.
But a small edition of this Map was printed, and the plates were then destroyed.
A few copies are for sale.
Price: On thick, heavy paper..... $25
On bond paper, for mounting..... 25
The six sheets can be mounted separately, or in a single roll 15 feet long by 42 inches wide.
Address,
THE SCIENTIFIC PUBLISHING CO.,
27 Park Place, P.O. Box 1833,
New York City.

VIRGINIA iron ores have appeared in Ohio as competitors of the products of Michigan and Missouri, and the result of the tests now making at Trenton are looked forward to with much interest.

MESSRS. POOR have, in their introduction to the forthcoming *Manual of the Railroads of the United States*, which they publish annually, given the weight of figures to the generally acknowledged statement that the newly-built railroads have been heavily loaded with securities. They show that, in the three years ended December 31st, 1882 the increase in share capital and indebtedness for old and new roads was $2,023,646,842, the increase in the funded debt being $864,929,029, and of the floating debt, $98,289,910. A little more than half of this, they estimate, is the actual cash expenditure made, the new roads costing only, on an average, $30,000 per mile, or $900,000,000 in all, while the cost of improvements of old roads was not more than $150,000,000. This leaves about $974,000,000 for "water," and sufficiently accounts for the loss of confidence on the part of the general public in the diluted railroad securities, and the men who have kept the printing-presses busy. Messrs. POOR take consolation from the fact that we have been taught a lesson, and that for the present we are not likely to fall into the same errors. They argue that it is a proof of the enormous wealth of the country, that its people have been able, almost unaided by foreign capitalists, to spend more than a million of dollars a day for three years in railroad enterprises, without feeling the strain more rapidly, and it might be added that, during the same period, they have contributed enormous amounts toward the same class of enterprises in Mexico, have been paying off the nation's indebtedness at a rate unprecedented, have indulged in a lavish expenditure of public funds of every description, and have invested uncounted millions in creating new industrial establishments. In miner's parlance, we have overdone the dead-work, and it will take some time to make it productive. It is encouraging, and that is a point which Messrs. POOR justly insist upon, that, in spite of much waste and wild inflation, the greater share of the work done has been of a permanent character. It has opened out wide stretches of new country; it has largely added to the means of developing our resources and rendering existing industries more independent. We have prepared the way for larger and more advantageous production, and are only temporarily suffering from the strain of over-exertion. We have been brought face to face with the problem how to solve the question of coping with the fact that we have no home market for a large share of our crude and finished products, and the sooner we intelligently attack the questions at issue the better. We can not afford to pay interest and dividends on double the actual outlay on our railroads; we can not hope to make returns of ten per cent annually on agricultural and manufacturing property run up in nominal value by frequent speculative turns; we can not expect to keep rickety or antiquated plants earning big profits, and expect every body else but ourselves to pay for it.

COMPUTING THE HEATING SURFACE OF HOT-BLAST STOVES.

Furnace-men in France and Germany have been for some time quite eagerly discussing hot-blast stoves, their advantages, their drawbacks, and the best method of overcoming the latter. The leading journals of the continent, *Stahl und Eisen*, *Le Génie Civil*, *Zeitschrift des Vereins Deutscher Ingenieure*, and others, have printed exhaustive articles in rapid succession, and a good many suggestions of value have been brought out. Among the most interesting contributions is an attempt by Herr STEFFEN to compute the heating surface required. We may briefly run over his figures, as reviewed by Herr FRITZ W. LUERMANN, a metallurgist whose name is thoroughly known in this country. Assuming that it is desired to ascertain the heating surface for two blast-furnaces, using each 75 tons of coke, or 150 tons together, deducting 15 per cent for ash and moisture, it will be necessary to consume 92·89 kilograms of carbon during every minute of the twenty-three hours actual blowing time. STEFFEN assumes that it will require only 4·3 cubic meters of gas per kilogram of carbon, a quantity which LUERMANN considers too low, as it would only convert the carbon into carbonic oxide. It should not, however, be confounded with the estimates made in computing the blowing-engine capacity, usually placed by German engineers at from 5·2 to 6·33 cubic meters. Taking the charge to be 1000 kilograms of coke, containing 850 kilograms of carbon, 2000 kilograms of ore, and 250 kilograms of fluxes, yielding 1097·46 kilograms of pig, STEFFEN estimates that 4266·15 kilograms of blast would yield 6054·12 kilograms of gas per 1000 kilograms of coke, or 3890 and 5516 kilograms respectively per 1000 kilograms of pig. If this quantity of blast were heated to 800 degrees Celsius, it would carry into the furnace 744 calories per kilogram of pig-iron. In this theoretical case, STEFFEN calculates the heat required per kilogram of iron at 3953 calories, of which 3209 must be furnished by the combustion of carbon. In reality, the 850 kilograms of carbon consumed per 1097·45 kilograms of pig-iron produce 6254 calories per kilogram of pig, so that only 51 per cent of the heat produced in the blast-furnace is actually used in the manufacture of pig; and deducting losses, 5·097 kilograms of gas per kilogram of pig-iron produced are available for other purposes, or, at the rate of production assumed, 607·56 kilograms of gas, containing by calculation 22·5 per cent of carbonic oxide and 0·5 per cent of hydrogen, capable of yielding per kilogram 715 calories, or 434,405 calories per minute. LUERMANN assumes that the 360 horse-power blowing-engine would require 1·5 kilograms of coal per hour per horse-power, or 12,420 kilograms per run of twenty-three hours; and that the hoists, pumps, etc., would want 2376 kilograms more—a total of 14,796 kilograms, or 10·65 kilograms per minute. Taking the value of one kilogram of boiler coal at 7500 calories, one kilogram would be equal to 10·49 kilograms of gas, so that the quantity of gas necessary for the boilers would be per minute 111·72 kilograms, leaving 495·84 kilograms of gas for the hot-blast stoves,

Digitized by Google

or 354,525 calories per minute. STEFFEN estimates the loss of heat in the stoves by radiation and by the temperature of the escaping gas at 40 per cent, so that 212,714 calories would be available per minute. He states that practical experience has shown that it is not advisable to go in cooling beyond one degree Celsius per minute. Assuming the quantity W of blast delivered into the furnace at a temperature of 12 degrees Celsius, the temperature to which it is to be heated T, the surface to be heated by the gas at 1·26 square meters per cubic meter of blast, the specific heat at 0·239, we have the formula:

$$1{\cdot}26 \times 0{\cdot}239 \times W \times (T - 12) = X \text{ cal.}$$

The product X calories must be equivalent to the cooling of the mass of fire-brick in the stove, and we have therefore the formula:

$$G \times 0{\cdot}25 \times t = X,$$

in which G is the weight of the masonry 0·25 its specific heat, and t the rate of cooling per minute in degrees, in this case 1 degree. From this the weight G can be calculated, and by calling the weight of a cubic meter of brick-work 1900 kilograms, its cubical contents may be ascertained. If the stoves work on gas twice as long as on blast, the thickness of brick which will cool may be assumed at 0·10 meter, so that the surface will be twenty times approximately of the cubical contents. Thus the needed heating surface, given consumption of fuel and production of pig per diem, may be roughly ascertained.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

The Boss Continuous System at the Total Wreck Mill, Arizona.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: As it is a matter that interests the general mining public, I wish to report our experience with the "continuous" system of pan amalgamation, at the Total Wreck Mill, Pima County, Arizona. The mill has a rock-breaker, twenty stamps, fourteen pans, and seven settlers. It was started on February 14th; one half of the mill on the Boss "continuous" system, and the other half on the old-fashioned or tank system. A rigid and exhaustive trial was made, extending over a period of forty-four days, with the object of determining positively which was the more profitable way for us to work our ores. The percentage yield from average assays was 84·12 per cent for the tanks, and 86·35 per cent for the "continuous" plant. The test was conducted with the utmost fairness. I do not know why the "continuous" system should have done better than the tank system, unless it is the stronger attrition of pulp against the quicksilver in the sharp current of thin pulp, or the constant meeting of the pulp with fresh quicksilver. Possibly it might have been both. Certainly there is opportunity for a more varied treatment and manipulation in the several pans of the "continuous" system than is practicable in one pan, by the old style of amalgamation.

The mill worked seventy tons per twenty-four hours, consuming in the same time 4½ cords of cedar wood. The loss of quicksilver from the starting of the mill averaged 1·10 pounds per ton. The loss per ton for the last two months has been but 0·90 of a pound per ton.

The large saving in labor and in fuel, the cleanliness, the reduced wear and tear, because of the steadiness of the load, together with a great many other favorable points, should make the "continuous" system of pan amalgamation a favorite one for the millman and mill-owner.

Respectfully, W. H. ARMSTRONG.

SAN FRANCISCO, CAL., Aug. 7.

The Drifton School.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: It may be of interest to some of the readers of the JOURNAL to obtain some items of the progress of the Industrial School for Miners and Mechanics, of Drifton, Pa., which has just closed its fourth annual session with its usual public examination on the 6th of August. The school opened with 34 scholars, and admitted four more during the session. During the session, eight scholars left of their own accord, and four were discharged for neglect of studies. The school closed, therefore, with 26 scholars. Their average standing in regard to attendance and progress in their studies has been:

Per cent in attendance.		Per cent in progress.	
Six from	90-99	Seven from	90-95
Eleven from	70-86	Eleven "	70-85
Six "	57-68	Seven "	50-65
Three below	50	One below	50

The Preparatory Class was examined in the English branches, geometry, and algebra, to simple equation of one unknown quantity.

The Junior Class was examined in algebra as far as quadratic equations and logarithms; geometry of solids, including volumetrical computations of solids of any shape; geometrical projection of solids, including conical sections and other cross-sections; mechanics, on friction, strength of materials, and dynamics.

The Senior Class was examined in practical geometry, applied to leveling and underground surveying; geology—the geological formations constituting our globe; constituents of rocks and determination of simple rocks during examination; mining—occurrence of useful minerals; description of mineral deposits; searching for mineral deposits; application of the drill for deep boring; excavation of useful minerals and rocks, including tools and appliances; power drills for driving and sinking; mechanics—hydrostatics and aërostatics.

Previous to the public examination, lasting over four hours, in the presence of Hon. E. B. Coxe, who selected the subjects for examination, and even examined some of the senior class, a four weeks' searching review took place, by constant questioning in the class. None of the subjects in which the scholars were examined was known to them during all this period. Examples of the work in drawing, free hand and mechanical, many graphically executed problems from surveying, and a map made by the senior class from its own field-work, as also a number of written problems in mathematics, mechanics, book-keeping, and compositions were open to inspection.

Generally, the scholars passed very creditably, and in various instances even very well. Seven prizes, consisting of useful professional books and instruments, were given to the best scholars. It is not more than right to say here that the interest the scholars take in their studies should rouse other individuals and companies to follow the noble example of the proprietors of Cross Creek colliery, and make this secondary education what it very usefully would be—the primitive education of our mechanics and miners. What a world of difference would this produce in our coal regions! Yours truly, OLD FREIBERG.

DRIFTON, LUCERNE CO., PA., Aug. 9.

MINING IN BOULDER COUNTY, COLORADO.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: During the last year and a half, mining has received a new impetus in Boulder County, mainly through the efforts of miners who were dependent upon prospecting for a living and a few private companies which still retained faith in the telluride veins. For years, the uncertainty of the existence of tellurium ores in paying bodies, at any great depth, deterred capitalists from going down upon their mines. This question has been solved by the American Consolidated Gold and Silver Mining Company, on the Slide vein in the Gold Hill District, where, at a depth of 600 feet, pay ore is found in a large body; also in the Melvina mine, where, at a depth of 500 feet, pay ore is found.

A great deal of attention has been given to concentration in all parts of the county, about as many processes having been used as have been invented; but, with the exception of the Frue vanners, of which there are thirty-seven machines in the county, and one set of Rouse tables—the latter a Colorado invention—all others are either in disuse or have been removed. The main difficulty in concentrating telluride ore is, that the specific gravity of tellurium ores is so small that it passes off in the sluices. The Frue vanners, however, when handled with skill, effect a large saving, and enable a quality of ore to be worked at a profit which was valueless a few years ago.

The Neikerk & Butch mill at Crisman, has recently purchased 1000 tons of the Grand View dump, which samples $21 per ton. The price paid was $1 per ton. The Century Company's mill, at Salina, will be ready for work in ten days, drawing its ore supplies from the Atchison, Fortune, and Melvina mines. This last-named property has recently passed into the hands of practical miners; and as the facilities for handling the water and rock have been doubled by a new plant of machinery, we have no doubt its almost unexampled record of a monthly expenditure of $2000, with an ore-production of $17,000, will not be lowered.

The American and Grand View mines, at Sunshine, are again at work, the former under lease; while the Inter-Ocean and Emancipation properties of the same place are steadily producing at a profit to their owners. With the Ella McKay, Winona, Little Pittsburg, Prussian, Horsfall, and Slide steadily at work, Gold Hill is making her regular shipments. Owing to delay in settling the estate of the former owner of the Cold Spring, which has been a steady producer for the last eleven years, the mine is closed down temporarily. Work has been resumed upon the Washington Avenue, and strong hopes are entertained that success will follow. This is one of those properties where thousands of dollars were spent in a mill before the ore-bodies were opened, only to find the ore of such a nature that the mill could not treat it; and after spending thousands to establish this fact, the works and mine were of course closed; mining in Boulder County thus receiving another blow on account of incompetent managers.

Mining matters are very quiet at Caribou. The Caribou mine is again passing through one of its periodical financial manipulations at the hands of a few of the principal owners, while the condition of the mine, as far as can be learned, is good. With the exception of Caribou, every camp in the county is more active than for years past, with good reports from all. Our millmen estimate that the output for this year will amount to at least $450,000. As no heavy sums of money are spent anywhere in the county, the above sum will pay handsomely for the labor expended.

Of course, our people realize that the Jamestown excitement was an injury to the county, in that it was simply a grab game originated by a few parties for the purpose of plucking Eastern capital. The camp has about settled down upon the old basis, which is the supply from five or six paying properties in the vicinity. JOHN R. WOOD.

BOULDER, COLO., Aug. 6.

A NEW SMOKE-CONSUMER.—Mr. John S. Barwell, engineer of William Glenn & Sons, of Cincinnati, has the latest and most simple smoke-consumer. On the bridge-wall, he constructs a section of tubes of fire-clay, the tubes two feet in length, with a diameter of two inches. He starts the fire with coke, and the tubes soon get red-hot, and then, no matter what fuel is used, the smoke disappears in passing the fire-clay tubes, and beyond them is pure white flame. The cost of the reconstruction of a furnace is about $15. The new smoke inspector has seen this "device," and is surprised at the efficacy of so cheap and plain a method of smoke prevention.

LAKE SUPERIOR NOTES.

Special Correspondence of the Engineering and Mining Journal.

The correction of my last iron letter by a Cleveland correspondent, whose name, if I mistake not the person behind the initial, is itself a pillar of strength, is an astonishing surprise to the mining superintendents of Lake Superior. The "Specular" article was based on a careful study of all the data at hand in this district, and reflected the positive assurances "from the inside" of the leading mines, and the best-posted correspondents of Eastern managers. If, as "P." says, nine tenths of the down ore have been sold, no one will be more surprised, and of course, none more gratified than the anxious superintendents of our peninsular properties, from whom this information appears to have been sequestered. It will even yet seem a little strange to them that their mines should refuse orders, as "P." asserts, because they are sold up, when none of the larger mines except the Barnum, which has sent down only 25,000 tons, is working strong, and many of them are doing little or no stoping at all. Some of the little fish, like the Boston, Winthrop, and McComber, may have sold up, and several of these doubtless are working somewhat strong. Only this week, the Republic was involved in a strike, on the ground that the mine had contracted for the delivery of from 150,000 to 175,000 tons; but the president, Mr. David Morgan, met the report with the public assertion that the mine had sold only 50,000 tons, of which only 30,000 tons were ore of the first class. Were it not a breach of confidence, other mines could be named whose unsold products at the time my former letter was mailed would reduce the proportion of the product of 1883 to so small a figure as to be a mere phantom—that is to say, of course, if the Western agents know any thing about what they are talking of. If, for reasons, however, the Western agents have been wrongly instructed on sales, it would illustrate the ancient proverb that some others than the Chinamen are peculiar for ways that are dark and tricks that are vain. Be this as it may, your correspondent has no debate with "P.," who is *in situ* at Cleveland, to avail himself, if he will take the trouble, of data which seem to be beyond the reach of the magnates of irondom; and if nine tenths of the down ore are sold (?), your correspondent is glad to modify his figures; and, having no axes to grind, no jobs to smooth over, no bribes to cater for, and no malice to execute, but existing solely to lay before the readers of the ENGINEERING AND MINING JOURNAL an account of the iron and copper industries of Lake Superior, which shall be wholly without bias, and as reliable as a patient study of all the facts can produce, he will be glad to have the "Specular" articles corrected in even the smallest details, at any point and at any time. This is said once for all.

Word has come up during the past few days of the sale of several blocks of ore, from 25,000 to 50,000 tons each, at Cleveland, and of a hardening in Bessemer prices as well. There is also a revival in demand for ores in Pennsylvania, the Scranton purchases discharging cargoes mainly at Buffalo. There is still considerable unsold ore at Erie—or was on the first instant. The outlook for future operations, however, is much better than even one month ago. Trade reports show a revival in demand for railroad construction and equipment, particularly in the building of locomotives—a fact which ought to exercise a marked influence on the price of copper ingot. The locomotive shops, says Mr. Swank's paper, have employed about the same number of men, up to the first ult., as last year; but reports from other sources show a visible increase during the past few weeks. The Bessemer mills report an increasing business. A director informs me that the Union Iron and Steel Mills, of Chicago, are about to go into blast. Thus far, moreover, we have not been very much troubled with the importation of steel and iron rails; the imports of steel up to July being less than thirty thousand tons, as against 101,000 tons for the same time last year, and the imports of iron only a trifle over 2000 tons as against 20,000 for last year. This shows that the market, such as it is, is pretty well held by American mills and American mines. The railroad mileage constructed during the same period of six months was 2032 miles, as contrasted with 4181 for the like period in 1882, and 1917 in 1881. If, however, the rate of increase during the remaining six months should equal that of 1882, the total mileage constructed in 1883 will not fall short of 5500 miles; and if it equals any thing like that of 1881, it will exceed by round figures 6000 miles. This is a crumb of comfort, and finds something of a basis for rational hope in a Wall street report which states that 9000 miles of track ought to be laid this year, and that over 15,000 miles are provided for. If, therefore, our home mills continue to hold the market, there ought to be a lively demand for ores, and the statement of your Cleveland correspondent, that the mines are sold up and are turning away orders, ought to be, if it is not already, literally true.

On the other hand, there is a disturbing factor in the figures of Mr. Swank, which show that, while our production of rails must have fallen off by perhaps one third, our production of pig has increased, being 2,311,662 gross tons for half of 1882 and 2,352,019 gross tons for the first half of 1883; and of this increase in production there were 528,590 gross tons unsold on the first of July, as against 383,655 gross tons at the beginning of the year. And yet it is to be remembered that the mills have been buying only in hand-to-mouth quantities, so that the amount of pig in the country may, in reality, be much less than the memory of the amounts in first hands in 1882 might lead us, at first blush, to infer. And in addition to this, Mr. Swank tells us that not over 5000 tons of foreign pig were in bond at all ports on the first of July, showing that its influence can scarcely reach beyond tide-water markets. We infer from these considerations that the future of our mines must, in the nature of things, be a large improvement on the past six months. The grip of the bears on railroad securities must be slackened in the event of a prosperous autumn, and the breathing of a new energy into railroad construction which must result as a consequence will start up our pig furnaces (nearly one half of which are out of blast), and this will mean a return of good times to our mines.

There are but few items of moment to be recorded in this letter. The Republic strike came to an end on Monday afternoon, the men carrying their point in the restoration of wages to the prices current through the Marquette District. The Champion has closed down for brief repairs to its hoisting-plant, but will be at work soon. Immense bodies of rich ore lie in the areas of the company's property; and although but little comparatively is doing, a general revival will see the Champion again at the front. Considerable exploring is going on in the vicinity of Michigamme, and a few rich finds are reported. The Michigamme mine itself is looking very well, and could, if required, make a decided advance over its record of the past. I notice in the Menominee papers that the Chapin intends sending down at least as much as last year; if so, it will be likely to be the banner producer of this calendar year—a distinction long held by the Lake Superior. It is reported that the Florence has shut down for good, and is allowing its pits and galleries to fill with water, although a letter from that place informs me that operations will begin again next spring. The mine sent down 160,000 tons last year, and was thought to be one of the most prosperous mines of the Menominee range. This will be a heavy blow to the handsome and thriving village to which it has given its name; but other industries will keep the blow from being fatal. A report comes up that Captain Goodrich is to begin operations at his mine in the Saginaw range, although operations for the present will be confined to forcing up a body of hematite which was found near the base of the bluff late last fall. A new find is also reported at the Jackson. The Iron Cliffs furnace is running both stacks, and is developing its mine some five miles from Negaunee, though hardly at high pressure.

The Menominee mines are pushing along, some being a little hard up for ore. Several of the mines are working somewhat strong, since they are owned by Pennsylvania and Ohio furnaces, which devour all their product. The Norway had rather a formidable cave some time since, a superficial area of not less than 115 by 150 feet going down about fifty feet. The upper levels are filling with poor ground, to prevent a spread of the fall, which would endanger the shaft and otherwise interfere with hoisting operations. Exploring is going on at a lively gait in "the range," and a party under Mr. C. E. Wright, a well-known engineer and mining expert, are thrusting their picks and geologists' hammers against the ledges of the vast Agogebic District, the results of which will be made familiar to you in the near future.

SPECULAR.

THE MANUFACTURE OF ZINC IN BELGIUM.*

By M. St. Paul de Sincay, Chenee.

At the epoch of the Roman invasion, the Belgians were already distinguished for their skill in the working of metals. Under the reign of Charlemagne, they understood their artistic treatment; and by the tenth century, they had acquired great skill in the casting and chasing of goldsmith's work, as is shown by the numerous and remarkable specimens preserved to this day. There is therefore nothing astonishing in their having been the first nation of Western Europe to understand and practice the manufacture of zinc. The continual communication which, from a very remote epoch, they kept up with the East by way of Germany, introduced into their country a new metal of a fine yellow color, and having the qualities of copper. This metal the Greeks distinguished by the name of *oreichalkos:* it had been produced from a remote period in Asia Minor and in the Isles of the Archipelago. The Belgians soon learned that it was made by alloying copper with a mysterious substance contained in calamine rock. This rock was probably known throughout a large part of Belgium, because both in the strata of the Devonian formation and in those of the Carboniferous era it formed numerous superficial deposits near the banks of the Meuse between Givet and Liége. Again, in a corner of the duchy of Limburg, not far from the Liége District and from the frontiers of Germany, there existed a bed of this mineral having an exceptional richness and extent. This great bed was subsequently named from the territory containing it, the Moresnet bed. It is generally admitted that here was the seat of the first working of calamine (carbonate of zinc); it is at least certain that at a very distant epoch this mineral was mined there, but the actual date when the working was begun has not hitherto been exactly determined. Ancient documents relate that calamine was raised in the neighborhood of Moresnet at the beginning of the seventh century. Under the date of July 5th, 1435, mention is made of the concession of a zinc mine accorded by the Duke of Limburg. In a record of 1439, a notice occurs of the calamine mountain "which the men of Aix were accustomed to work." This working, at that time abandoned, must have dated from a very distant period. From this circumstance the calamine-bed where it existed received afterward the name of Vieille-Montagne or Altenberg. In 1454, the working of this mine was recommenced according to a concession made by Philippe le Bon to the Sieur Arnold Van Zevel. This mine, which must have been so long in existence, was at that time the most esteemed for the abundance and the quality of its products. These were calcined, or burnt, as it was then called, on the spot; for which purpose wood-charcoal was employed, made in the Forest of Hertogenwald. Thus prepared, the ores were sold, and transported to different localities where copper was beaten. Such works existed at Aix, at Stolberg, and at Cornelius-Munster; but the brass-works of Dinant, Bouviegnas, Oignies, and other localities, near Namur, bought a greater quantity of the make, and transported it to their works on carts as far as Visé, whence they made use of the two great rivers, the Meuse and the Sambre.

It is known that they prepared the yellow metal by mixing in crucibles red copper from the Tyrol, and calamine, after an addition of charcoal; they then transformed the brass, whether cast or hammered, into articles of all kinds, which were known under the name of Dinanderies. Specimens of these are still existing, and bear testimony to the remarkable skill of their artists. Thus there is reason to believe that the working of calamine in Belgium began at about the same time as the making of brass, and was already practiced in the twelfth century. For a long time, under the dukes of Limburg and of Burgundy, and even the Spanish princes, the mines of the Moresnet District were let to mining companies under temporary concessions, not extending beyond twelve years. At certain periods, the government, from motives of policy or otherwise, preferred its own management to the system of leases, and worked mines by its own officers and to its own profit. This was especially the case under the Archdukes Albert and Isabelle, and later in the time of Philippe IV. of Spain. The Austrian government, like the Span-

* A paper read at the Liége Meeting of the Institute of Mechanical Engineers.

Digitized by Google

ish sovereigns, used sometimes the practice of leasing and sometimes of working on its own account. The raising of calamine was considered from the first as an important branch of national industry, as is best proved by the numerous regulations to which it is subjected. In order the better to insure its development, the public authorities went so far as to interdict the importation of foreign calamine. After the annexation of the Belgian provinces by France in 1795, the government of the republic itself worked the Vieille-Montagne mine for the profit of the nation; but this attempt at government working soon produced a great diminution in the returns. Hence it was speedily renounced, and in 1806 the mine was let to Daniel Dony, of Liége.

Up to this period, Belgian calamine had only served for the making of brass; but for some time the question had been agitated of abstracting from it the metal which it contained, and which laboratory experiments performed at Liége about 1769 (especially by Professor Villette on the instructions of Magraff) had shown to be of excellent quality. The object was to replace by a national product the zinc made in the foundries of Germany, and also the "tutenag," an impure zinc brought by the ships of England and Holland from the farthest East. The progress which chemistry had made, thanks to the labors of Lavoisier and other scientific men, had spread widely the taste for research and experiment. From different quarters, attempts were made to discover a new method of working zinc, appropriate to the nature of the Belgian ores; and under this impulse, the government imposed on its lessee, Dony, an obligation to make "such experiments as might be judged useful, in order, by the aid of suitable furnaces, to reduce the calamine to a metallic state." Dony accepted these conditions, and set resolutely to work. The task was a difficult one. It required long effort, great expense, and numerous attempts; but the original and persevering genius of Dony overcame all difficulties, and on December 7th, 1809, he applied for a patent for fifteen years, "for the construction of a furnace suitable to extract zinc from calamine, and for the processes employed in this operation." This patent was accorded to him by imperial decree on January 19th, 1810. The Liége method of reducing zinc ores was now discovered, and Dony had given his country a new industry, which was destined to have a vast development.

The small establishment which he had founded at Liége, in the Faubourg St. Léonard, in order to carry out his researches, became the first zinc-works of Belgium. The second furnace was started on January 28th, 1810. The position of this foundry was excellently chosen, placed between two populous suburbs and in the neighborhood of the collieries. It was also able to make use of two main roads and of the Meuse, to receive its raw materials and to deliver its products. This establishment played an important part in the history of Liége. After numerous vicissitudes, it was closed in 1880. A square and several streets have been built on its site, the names of which will still preserve the recollection of the principal authors of the zinc industry and of the main site of calamine working in the district. The discovery of Dony had cost the inventor considerable sums for his experiments. He was recompensed by the protection of the authorities and by the praises of scientific men; but this was not sufficient to restore his broken fortunes. Metallic zinc was at that time applied to very few purposes. Dony hoped to find a market for his metal with the brass-founders; but these, influenced by routine, preferred to treat their copper by means of calamine, as their fathers had done before them. This failure imposed upon Dony further efforts, and a second task still more arduous than the first. After having discovered the method of producing zinc on an industrial scale, it was now become necessary to find applications for it, and to promote its use. In one word, the newly-obtained metal had to find its place in the ranks of ordinary and necessary materials. Indefatigable as ever, Dony set resolutely to work, but the effort was beyond his power. He associated with himself for some time the Sieur Chaulet; but in 1818, completely ruined and worn out by his labors, he definitely resigned in favor of Dominique Mosselman. The latter gave a strong impulse to the zinc trade; but despite his great powers and rare energy, he did not succeed any more than Dony in bringing to completion the work which he had undertaken. In 1837, his sons took up the task, and formed with their father the Société de la Vieille-Montagne. The resources of the new company were considerable; in the first place, it possessed the great calamine concession whose name it bore, and comprehending the whole Moresnet District. Next, it possessed two foundries in actual work—that of St. Léonard, which was now considerably enlarged, and another recently erected near the mines in neutral territory. A third zinc-works, then in course of construction at Angleur, on the left bank of the Ourthe, also belonged to them. In 1837, the first two of these foundries produced together 1833 tons of zinc; the next year, the Angleur works contributed to the production, which rose to 2540 tons. Thanks to the creation of new markets, the make of zinc then received a large development; new furnaces were built, and the production of the three works of Vieille-Montagne advanced rapidly from year to year; as is shown by the following table, which gives the production of the zinc-works at Moresnet, Angleur, and St. Léonard, from 1839 to 1852:

Year.	Tons of zinc.	Year.	Tons of zinc.
1839	3,336	1846	6,720
1840	3,631	1847	6,156
1841	3,891	1848	6,060
1842	4,508	1849	7,844
1843	5,105	1850	9,180
1844	5,665	1851	9,755
1845	5,941	1852	10,372

By the annexation of several competing works, the Vieille-Montagne Company has seen its production increase from year to year, until in 1882 it reached a total of 39,000 tons of raw zinc, 36,000 tons of which were made in Belgium.

During the same period, several new establishments for zinc-working were founded in Belgium. Among the first of these should be mentioned the Nouvelle-Montagne Company, founded in October, 1845. The two works of this company, situated one at Prayon, near the Vesdre, and the other at Engis, on the Meuse, produced in 1846 about 1357 tons of raw zinc. They were supplied with calamine from the royalties of the Nouvelle-Montagne, which was situated between Verviers and Stembert, and from the beds at La Mallieue and Les Fagnes, near Engis. The first of these mines was leased on May 7th, 1829, and the second on May 17th, 1830. The working of calamine at La Mallieue has existed for a long time; the brass-makers of the Namur District took their supplies thence at the beginning of the seventeenth century. It was in exploring along a bed of carboniferous limestone, with the object of working alum slate, that calamine had been met with: it was associated with ores of lead. The annual yield of these Nouvelle-Montagne zinc-works rose gradually; in 1865, it attained 3749 tons; it then sank below 3000 tons; but rose rapidly from 1874, and has now reached the figure of 6650 tons.

In 1882, the Prayon works were separated from the Nouvelle-Montagne, and restarted by a new company, bearing the name of Société Anonyme Métallurgique de Prayon.

In 1841, metallurgical works were erected in the commune of Antheit, near Huy, for treating the ores of zinc and lead derived from the Corphalie mines, which had been conceded in June, 1829. A company was formed July, 1849, under the name of the Société de la Corphalie, to continue the working of these mines. The company also possessed the right of exploration in the calamine-beds of Sielles and of Landesme-sur-Meuse, especially at the place called Hayes-Monets; this concession was obtained in February, 1848. The production of raw zinc at the Corphalie works was below 1000 tons up to 1847; it then rose from year to year, and in 1869 reached 6112 tons. After a period of reverses, it took a new departure in recent years, and is now above 8000 tons. In 1863, the Corphalie Company, being amalgamated with a zinc mining company situated in Croatia, changed its name to that of the Société Métallurgique Austro-Belge.

At the same date, the firm of Laminne, of Liége, founded at Ampsin, a zinc foundry on the banks of the Meuse, and also works for calcining zinc ores at Bende, on the plateau which overlooks the Meuse on the side of La Hesbaye. The foundry turned out 1181 tons of metal in 1856; but owing to the development of its capacity, it is now able to supply more than 6000 tons per annum.

The Grande Montagne Company was formed in 1846, to work the zinc-bearing beds of Flône, and built in this district works which were started in the succeeding year, and which, after some vicissitudes, were taken over by the Vieille-Montagne Company in 1853. It was then supplied by ores from different mines, like the other foundries of the same company. In 1854, its production was not more than 1510 tons; since that date, it has quadrupled itself.

The Société Anonyme des Houillères et Fonderies de Zinc de Valentin Cocq was founded like the last in 1846, and was merged at the same time in that of the Vieille-Montagne. Its works are situated at Hollogne aux-Pierres, and at that time already produced 2391 tons per annum. The production has since developed rapidly, and now reaches nearly 18,000 tons. The Valentin Cocq foundry is certainly the largest zinc-works in Europe.

The Société Anonyme de Zinc, Blanc de Zinc, et Charbonnage, de Colladios was founded in 1855, and built at Mons, near the Valentin Cocq foundry, zinc-works, the make of which was always below 500 tons. This foundry was bought by the Vieille-Montagne Company in 1865, and joined to the great works of Valentin Cocq.

The Société de Bleyberg-ès-Montzen added, in 1855, a zinc foundry to its lead-works, in order to treat the calamine of Schimper, as well as blende extracted from its great vein of lead, and found associated with galena. This foundry, whose annual make has for a long time been only about 1500 tons, has recently received great enlargement, and its capacity is now about 5000 tons.

The zinc-works at Ougrée, now belonging to Messrs. Escher, Ghesquière et Compagnie, dates from 1859. Its annual make, which was for several years small, is now above 4000 tons of raw zinc.

The most recent works in Belgium are those of Messrs. Dumont Frères, of Liége, erected in 1875, at Sclaigneaux, near their lead-works. It has developed rapidly, and its annual capacity is already as much as 6000 tons of zinc.

On the whole, it appears that Belgium now possesses eleven works for reducing zinc ores, and all in a state of high activity. Their capacity was developed gradually, and in 1882 they were able to turn out 71,565 tons of raw zinc. The following table gives the distribution of this total make:

Works.	Tons.
Vieille-Montagne	35,940
Austro-Belge	8,099
De Laminne	6,255
G. Dumont et Frères	5,500
Nouvelle-Montagne	5,480
Bleyberg	4,647
Ougrée	4,144
Prayon	1,500
	71,565

This total figure represents about one third of the whole production of Europe, but will probably be considerably surpassed in 1883. In so active a state of trade, it is not to be wondered at that the annual amount of ore consumed is considerable; it is, in fact, about 200,000 tons, only a part of which is furnished by the mines of the country. Belgium, as we have said, is rich in zinc-bearing strata; some of them consist of calamine, others of the blende, mixed with sulphates of iron and of lead. The greater part of these are under concession, and are worked to a greater or less extent. The principal concessions have already been mentioned; the others would form a long list which it is not worth while to give. For several years, calamine (carbonate of zinc) has been the only ore treated in the Belgian zinc-works. The preference thus given to it is easily explained by the facility with which it lends itself to metallurgical operations. For a long time, it was believed impossible to utilize the blende (sulphide of zinc); but thirty years ago, the making of zinc began to be largely extended, and it was necessary to have recourse to new supplies of mineral. Attempts were then made to make use of blende; special workshops were constructed for the desulphurizing of the new ore, and before long a considerable proportion of this ore was supplied to the foundries. In Belgium, the chief works for roasting blende are those of Bleyberg, Engis, Flône, Ampsine, Corphalie, and Sclaigneaux.

It would be difficult to estimate the quantity of zinc ores, carbonates and sulphides together, which have been extracted from the Belgium mines. It must be very great, since from 1837 to 1882 the mine of Moresnet Neutre alone, belonging to the Vieille-Montagne Company, produced

Digitized by Google

1,295,290 tons of calamine. The calamine earths, which are found with the ore-bearing rock, are generally very poor in zinc, but are made more serviceable by washing. The same is the case with the blende, which must be separated from the other sulphides with which it is almost always associated; but on account of this separation, the mechanical preparation of blende gives rise to operations which are usually of a very complicated character. Belgium possesses several large works for the mechanical preparation of zinc, such as those of Moresnet, Welkenraedt, Bleyberg, Engis, Flône, Bende, Corphalie, and Sclaigneaux. These have a high reputation for the excellence of their manufacture. In several of these, appliances which are now known and appreciated throughout the world have had their origin. Except the Morsenet works, which only treat calamine from the neutral territory, all the Belgian foundries receive a part of their supplies of ore from abroad. It was the mines of Spain which first came in to aid in their supply; to these were subsequently joined those of Sardinia, Greece, Algeria, Sweden, France, Germany, and England.

Foreign calamine is generally calcined before being shipped; blende, on the contrary, is usually shipped in its raw state, and has to be submitted in Belgium to the preparatory treatment which its nature requires. Almost all these ores are brought by sea to Antwerp, where several agencies exist to receive them and to direct them toward the zinc-works, whether by railroads, with which all the works are connected, by canals, or by the Meuse; most of the works being equally accessible by the latter channels.

The Belgian foundries require from abroad nothing more than a supply of ore; for every thing else, they find in their own country and neighborhood all the resources necessary. Situated in more or less close vicinity to numerous collieries, they can choose the bituminous coal best suited to the system of furnace they have adopted. They receive from different sides, both from the basin of the Charleroi and that of Liége, non-bituminous coal and small coal, which they employ for reducing purposes. It is well known that, for the manufacture of zinc, as for many others, the question of refractory materials is of very high importance. The Belgian works obtain from large beds near Ardenne a refractory clay, with which they manufacture articles of an excellent quality and of long-established reputation.

But the special strength of these works lies in the fact of their possessing a class of workmen, strong, intelligent, experienced, active, well-disciplined, fond of their trade, and deeply penetrated with feelings of duty. Among this industrial population, which, without counting laborers, numbers some 7000 workmen, there are many who have saved enough to buy the houses which they inhabit, and the gardens which, after the rough labors of the shop, they find time to cultivate. The workmen at the Valentin Cocq works belonging to the Vieille-Montagne Company are distinguished in this respect, since at least half of them are proprietors. This love of property and care for the future is nothing surprising. For a long time past, the company has done its best to inspire this feeling by creating institutions of thrift intended to insure the material, moral, and intellectual good of the working-classes.

The first care of the company was to give all its workmen a share in the wealth which they procured proportional to their efforts and their success. The arrangements as to wages and allowances were made in this spirit. Subsequently, the work was completed by establishing the following institutions, all intended to ameliorate the condition of the workmen, namely: A sick fund, a provident fund, a savings-bank, and a life insurance fund. The first two are workmen's institutions in the full sense of the word; the sick fund is formed entirely by a sum deducted from the workmen's wages, and is used to supply their present needs in case of sickness or injury. The provident fund, which is supplied by payments from the company, is intended to provide for the future need of the workman when age or infirmity renders him incapable of labor. This solicitude for the working-classes on the part of the Vieille-Montagne Company has been imitated under different forms by the other Belgian works; and these measures have received a practical sanction which is worth noting—namely, that, so far as the writer knows, this industry has been wholly free from those strikes which have so often brought disaster into the trades of the miner and the iron-worker.

THE METALLURGY OF ZINC.

The different processes for the reduction of zinc ores are well known. The *per descensum* process has scarcely ever been practiced except in England. On the continent, the methods in general use are the Liége method and the Silesian method. Neither of these since its commencement has undergone any essential change, and they may be employed at present side by side with each other. The Liége furnace is generally higher than its width, and contains six, seven, or even eight ranges of crucibles. These furnaces occupy little space, and also consume less fuel than the Silesian furnaces. The latter, on the other hand, are cheaper as regards labor and the durability of the distilling apparatus. To complete the essential distinctions between the two, it may be said that the Silesian furnaces are specially adapted for treating poor ores; and this should be so, since they were invented to reduce the calamines, low in proportion of metal, which are worked in Silesia.

Belgium, as might be expected, has remained faithful to the Liége or direct-heating process, inaugurated by Dony. The works of Valentin Cocq and Flône are the only ones which possess furnaces agreeing with the Silesian system in their mode of heating; but being provided as they are with crucibles in three ranges, they share equally the advantages of the Liége method. Great efforts have been made to perfect the metallurgy of zinc. These have opened the way to progress in many respects. In all the operations required—in the preparation of the refractory materials concerned, in the crushing of the ores, in the composition of the charges, in the construction of the hearths, in the arrangements and dimensions of the heating chambers—important improvements have been realized: in all, new and improved appliances have come into use, which, for the most part, are due to eminent manufacturers in the district. Above all, changes have been made tending to render more easy and less dangerous the labor of the workman. Thanks to other improvements, the results of the process have been sensibly improved. It has especially been sought to augment the production of the furnace, to reduce the "écart" or loss of metal during treatment, and lastly to diminish the consumption of fuel. In all these ways, notable progress has been realized. The zinc vapors formed in the crucibles are condensed in receivers, made of refractory earths and called tubes or bottles. From these, the liquid metal is withdrawn, either several times during the operation, or once for all at its termination, and it is immediately run into ingots or rectangular plates, of a thickness from 20 to 25 mm. (0·8 inch to 1 inch) and weighing about 20 kilograms (45 pounds).

The first products of the distillation are collected in the form of dust, more or less oxidized, in wrought-iron pipes which form a prolongation of the tubes. This dust, to which has been given the name of gray oxide, must be submitted to a fresh treatment, unless it can be utilized directly for painting, or for the making of hydro-sulphite of soda. The second treatment is sometimes carried out in a furnace with vertical retorts, which bears the name of its inventor, M. Montefiore, and which is worked particularly at the Corphalie manufactory. The ingots of raw zinc are, some of them, taken to a rolling-mill and rolled into sheets. Others are reserved for making oxide of zinc, and others, lastly, destined for different industries, such as the making of brass, are sold in the condition in which they leave the foundry.

ROLLED ZINC.

The uses of rolled or sheet-zinc are numerous and varied. New uses are created every day. The consumption of rolled zinc, which has long been large, increases continually, and the greatest part of the zinc produced in Europe is not used until it has been passed through the rolls. The rolling of this metal at first encountered very great difficulties. These arose from the fact that its malleability is confined between very narrow limits of temperature. For this reason, the rolling of zinc will always remain a delicate operation, which can only be intrusted to experienced hands. The most suitable temperature is about 100° C. = 212° Fahr., and this must be maintained through the whole of the process. Below this point, the metal opposes too great a resistance to the squeezing action of the rolls, and it must be re-heated, which is a matter of much inconvenience. Above this point, it becomes brittle; at 200° C. = 390° Fahr., it can be brayed in a mortar. Whatever its method of manufacture, zinc ought to be re-melted before being rolled into sheets. The heat of fusion varies between 400° and 500° C. or 750° and 930° Fahr. Re-melting is generally accomplished in a reverberatory furnace. Its first advantage is, that it rids the zinc of the impurities, especially lead, which almost always accompany it. Again, the thickness of the ingots must vary with the final dimensions required; this is another consideration which renders re-melting indispensable. The re-melting plates are first roughed down or rolled between heavy rolls; then, after being cut down to a fixed weight, they are conducted to the finishing train, where the rolling is completed. There are, therefore, two distinct operations—the roughing down and the finishing. Between the two, the sheets should be re-heated in annealing-boxes placed upon the melting-furnace, so as to utilize the waste heat. Each of these operations gives rise to a production of scrap, which is more or less large according to the quality of the metal and the tenacity of the sheet. This scrap and any defective sheets are re-melted with the ingots coming from the foundry. On leaving the finished rolls, the sheets are cut by shears to a rectangular shape and to the dimensions required by commerce. There are several systems of shears; those most used in Belgium are the lever shears and the guillotine shears. The later, which at present have the preference in the rolling-mills of the Vieille-Montagne Company, cut the metal perfectly clean and exact.

After being squared, the sheets of zinc are sorted with great care. Those which are found to answer all the conditions are impressed with the stamp of the works. The thickness is specially gauged, and is expressed by a number on a fixed scale. It varies between 0·05 millimeter and 4 centimeters (0·002 inch to 1·575 inches). Zinc sheets are delivered sometimes loose, generally in barrels or boxes; hence a cooperage is an indispensable adjunct to a store for rolled zinc. This accessory is mentioned on account of its real importance. Belgium manufactures annually nearly 40,000 tons of sheet-zinc. The rolling-mills which contribute to this production are, in the first place, those of the Vieille-Montagne Company at Angleur and Tilff, which together furnish nearly 20,000 tons per annum. The remainder of the make is divided between the works of the Nouvelle Montagne Company, at Engis; those of the Société de Prayon, at Prayon; those of MM. Francotte-Pirlot & Co., at Chênée and Liége; those of M. E. Nagelmackers, at Chaudfontaine; those of M. Charles Heptia-Hauzeur, of Fraipont; those of Madame Veuve Bonhomme, at Nessonvaux; those of MM. Lejeune Frères, at Stère; those of M. L. Dacier, at Liége; those of M. J. Brasseur, at Huy; and those of M. G. Schmidt, at Brussels.

As already stated, the applications of rolled zinc are numerous and varied. We confine ourselves to a few. The making of roofing sheets certainly occupies the first rank. The systems vary according to the character of the buildings to be covered. For dwelling-houses, choice may be made between plates having the shape of a heart, a lozenge, a fish-scale, a rectangle, etc. All are recommended by many advantages; among which should be specially noted their complete impenetrability to water. Roofs for industrial buildings are generally constructed of fluted or corrugated zinc. Among other applications, some of the chief are the sheathing of vessels; the making of domestic utensils and articles for various trades, for many of which the zinc must be previously pierced with holes; the glazing of paper; the making of taps and of wire. In thick plates, zinc is chiefly employed by engravers for zincography, in arsenals for coating bullets, and in steam-boilers to prevent incrustation.

OXIDE OF ZINC.

Zinc heated to a red heat is evaporated, and the vapor coming in contact with air is oxidized and produces a white impalpable substance, which alchemists named *lana philosophica*, and which in modern times bears the name of "zinc-white." This oxide has long been employed for decorative painting. Its brilliant whiteness, combined with the fact that it does not change by the action of the air, and has no ill effects on the workmen who use it, are the principal qualities which have made it the most formidable rival to white lead. In making oxide of zinc, there are two processes, equally simple. The sublimation process is the most ancient. To sublime or volatilize ingot zinc, it is placed in a series of retorts within a common furnace; the oxide is formed in an exhaust-

Digitized by Google

chimney, and then passes through a long series of passages and condensing-chambers. It is deposited in large tanks of sheet-iron or cloth, which are ranged all along the path pursued by the vapors. At certain hours in the day, the oxide is collected into casks, and then, after the quality has been tested, it is compressed into barrels carefully made, ready for delivery. According to the purity of the metal subjected to the process, the zinc-white is obtained varying in color and brilliancy. "Blanc de neige" is a product of the most superior quality, and can only be made with zinc from the ores of the Moresnet beds. "Blanc No. 1" is the most common variety. It requires for its manufacture zinc coming from selected ores, and generally purified by re-melting. Lastly "Blanc No. 2" is the common variety, distinguished from the others by its shade of whiteness, though still identical in composition.

In the making of zinc-white, as in all other manufactures, residues are produced: drops of metal imperfectly oxidized, deposit in the retorts, and waste from the workshops, and all classed separately; then after being ground, washed, and dried by being led through winding passages, they form the "gris-pierre," which is employed in painting to replace minim. The second process for making the zinc-white is known as the American method. It uses the ore directly, and is necessarily therefore cheaper than the former; but its products are of inferior quality to those produced by sublimation. There are in Belgium only two works for making zinc-white. The Vieille-Montagne Company produces annually at the Valentin Cocq works 3000 tons of zinc-white by sublimation. The other work is at Ougrée, and belongs to Messrs. Eschger, Ghesquière & Co. There the American method is employed; but at present, the works are standing idle.

DIRECT USE OF INGOT ZINC.

As we have said, zinc was employed in the arts long before it was known in the metallic state. As of old, the making of brass continues to absorb the largest quantities in Belgium, and above all in England. Melted zinc is also used to cast ornaments and objects of arts, such as statuettes, groups, etc., which are afterward covered with copper by means of the galvanoplastic method, and imitate bronze with a perfection which defies the most skillful eye. The Vieille-Montagne Company makes from the ores of Moresnet, under the name of *fonte d'art*, a variety of zinc which is specially reserved for this purpose. Lastly, the galvanizing of iron, telegraph wires, etc., is a large source of employment for ingot zinc.

If the zinc-works of Belgium receive a part of their supplies of ore from abroad, in return their products are exported into all the countries of the world. France and England are those which receive the most; Germany, Italy, America, Scandinavia, and Holland also take their share.

In conclusion, the manufacture of zinc, the origin of which in Belgium dates back to so remote a period, has received from the beginning of this century a very large development. By the number of establishments devoted to it, by the quantity and value of the production, by the multitude of workmen it employs, by the importance of the capital which it absorbs, it holds one of the foremost places in the great industrial life of the country. In spite of the depreciation in value of all metals, the production of zinc increases from year to year, and the financial results of the operation are, in general, satisfactory. The working of zinc has a brilliant past, and it may be hoped that it will still enjoy in Belgium a long era of prosperity.

MAKE OF CRUDE ZINC IN EUROPE SINCE THE YEAR 1860.

DISTRICT.	1860.	1865.	1870.	1875.	1880.	1882.

The discussion on the paper was opened by M. Rocour, who pointed out some of the difficulties in connection with the zinc manufacture, and said he could not assent to the conclusion of M. Sinçay, that the financial results of the operation were, on the whole, satisfactory. He was, he said, of a contrary opinion, and if he could establish that view of the case, he should be doing the best he could for his own country, and for others that might be thinking of introducing the industry. They were largely dependent upon foreign ores. In 1882, the production in Belgium was about 83,000 tons, while the foreign imports amounted to double that quantity. The price of the ore was continually increasing, and the competition of the different works was so sharp that the margin of profit was very small. During the last three years, it would appear from the value of the shares at the present time that the result of the total working had been a loss. It might seem at first sight that the metallurgy of zinc was very simple, and might be carried on in any country; in reality, it was of a very difficult character, requiring men of special intelligence and training, and also of great industry. He thought that the industry was certainly not adapted to England, as the work had to be continued without intermission; indeed, he knew of works where the men were occupied three hundred and sixty days in the year.

Prof. Chandler Roberts, of the Royal Mint, said that whatever view might be taken as to the immediate prospects of the zinc industry in Belgium, there could be no question that the Belgian method had entirely displaced the English, and had found a home in Swansea. He had recently visited some large works there, in which the Belgian system had been entirely adopted. A large staff of Belgian workmen had been employed by the proprietors, and he fully indorsed the views that had been expressed as to their skill, industry, intelligence, and discipline. There had been a great difficulty in the use of regenerative furnaces as applied to the metallurgy of zinc, and he believed it had arisen from the fracture of the retorts, giving rise to the escape of zinc, which rapidly became oxidized and choked the regenerator. He should be glad to know if that difficulty still existed, and whether any of the hitherto abortive experiments for the extraction of zinc in the blast-furnace had succeeded.

Mr. B. Sharpe said that great difficulty had been experienced in working up certain sorts of zinc. They had generally flakes of lead underneath, and there was nothing that made brass more rotten than lead: it gave it a white fracture; in certain forms, sheathing for example, it would not wear as well; and it was bad in every way. But by taking the zinc and lead mixed, getting it to a temperature above the melting-point of lead, but below the temperature at which zinc volatilized, casting it in a vertical mold slightly rounded at the bottom, so that it would not crack, and letting it cool slowly, the ingot could be dropped, and the two pieces would come separate. He had often adopted that method when he had a quantity of bad spelter. With regard to the catching of the oxide, he had brought out a plan about ten years ago in Birmingham, by which he used a jet of steam, and injected the entire contents of the furnace into water: it was a modification of Giffard's injector. There was a large vat, and about four inches below the surface of the water a plate perforated with sixteen holes. With an 18-inch pipe, the products of the water were injected down the shaft; they went under the plate and came up through the holes. It was then found that what went away, instead of being thick with fumes of oxide of zinc (representing in one works that he knew a loss of £5000 a year), was an almost colorless gas, and at the bottom there was a sort of gray mixture deposited, consisting of unconsumed gas and oxide of zinc. Of course, it was valuable, and it could be recovered by depositing; but he gave up the plan for the simple reason that, although he was able to catch 90 per cent of it, apparently saving £5000 a year, it cost £5000 or £6000 a year to catch it. Scientifically, it was a great success, and if he had had the means of utilizing waste steam, it would have been a success financially; but where the steam had to be made separately, it was otherwise. In open-air furnaces, the products of combustion could not be run through a boiler for many reasons, the chief one being that it interfered with the draught of the furnace, and the mixture was not as regular as was desired. In certain qualities of brass, a difference of half of one per cent in spelter would make the difference between a good and a bad result. With regard to the shape of the ingot, there were various reasons why it should be preferable to cast in a circular form—he would suggest a size of three or four inches; the only objection was, that that was an awkward size to break into small parts. With circular casting, there was a smaller loss than putting into pots. In the case of air-furnaces, they were put in on a rabble: one of the great advantages was, that very little zinc was lost. The cost of the workman's wages might be saved several times over. If there were a lot of flakes three quarters of an inch thick thrown in on the top, there was a great loss. If made in a circular form and dropped in vertically by a pair of claws, there would be an immense saving to the makers. At one time, he thought it was worth while to adopt that circular form, and he thought that any one who took up the plan would get some orders to start with.

M. Rocour said with reference to the breaking of the retorts, that it has been generally found that the clay retort resisted much better with the gas regenerator than with the old fire-clays. The system of blast-furnace working for spelter has been tried in Belgium several times, but not during the last twenty-five or thirty years. Several trials had been made, but they had not been successful. The reason was, that when the current of spelter and carbonic acid came together, the spelter reduced the carbonic acid, so that they could only have in the mixture pure oxide of carbon and spelter. He did not know any kind of industrial furnace that could solve the question. They had never seen a furnace producing only oxide of carbon and nitrogen. In the present state of technical science, he believed the problem was insoluble. There was also another reason arising from the difficulty of condensation of a rather small quantity of spelter vapor, with a large amount of other gas. That was another drawback; but the first one was quite enough to discredit any other method of producing spelter than in a retort.

A MINE ON PAPER.

Judge Brown, of the United States District Court, sitting as Circuit Judge, has rendered an important decision on a motion to remand to the State Courts the action of Sylvester H. Langdon and others *against* Francis A. Fogg and others, originally brought in the Supreme Court of this city by plaintiff, as stockholder in the Silver Era Mining Company, in behalf of himself and all the stockholders. The company was organized under the laws of the State in February, 1880, to have a capital stock of $10,000,000, divided into 100,000 shares of $100 each. The defendants are the corporation and five individual defendants, alleged to have been the trustees of the body at the time of its formation and during the first year afterward. Upon the petition of Mr. Fisk, one of the defendants, a resident of New Jersey, action was removed to the Federal court. The complainant alleges that the defendants agreed with Henry S. Sanders to issue to him the whole of the capital stock in consideration of his conveying to the corporation certain mining claims and property in Arizona. It is further alleged that shortly afterward all of said stock was turned over to the individual defendants upon payment of $45,666.67. It is also alleged that the defendants, assuming to act for the corporation, issued certificates of stock, representing them to the public to be full-paid stock. Some of this stock on such representations was purchased by the plaintiff, who subsequently learned that the corporation had no means of developing or improving the property, and failing to work it, it had become forfeited and passed beyond the control of the corporation. It is also alleged that the individual defendants have not accounted for the difference between the ten million dollars represented by the capital stock and the actual cost of the property conveyed to it by Sanders. Judge Brown says it does not appear that the corporation ever had any property or capital whatever except the mining property which the defendants individually procured from Sanders, and any profits on sale of stock were individual and not joint transactions. The court denies the motion to remand.

THE SCHWARTZKOPFF SAFETY APPARATUS FOR STEAM-BOILERS.

By C. A. Stetefeldt.

Read at the Roanoke Meeting of the American Institute of Mining Engineers.

If we inquire into the causes of explosions of normally constructed steam-boilers, we may classify them under the following heads:

1st. Low water-level.
2d. Undue pressure.
3d. Firing empty, and injecting water after the sheets have reached a high temperature.
4th. Those still unexplained phenomena, known as "Siedeverzug" or retarded boiling, that is, the condition in which the water has reached a higher temperature than the pressure indicated.

Mr. Richard Schwartzkopff, of Berlin, Germany, has invented an apparatus which indicates every one of these dangerous conditions. The principle upon which its construction is based is this: An alloy, fusing at a certain temperature, closes, when fusion takes place, an electric current, having one or more alarm-bells in the circuit. Let us examine the ingenious manner in which Mr. Schwartzkopff has utilized this principle.

The apparatus consists of two parts, of which one is stationary and the other movable. The former serves as a receptacle for the latter. Fig. 2 represents a vertical section of the stationary part, fastened to the boiler, as shown in the drawing. The tube i, i is closed at the bottom, and reaches nearly to the flue or flues. A second tube a, a, concentric with the first, and sufficiently large to form an annular space, is open at the bottom, and ends at low water-level. A short distance above the crown-sheet, the second tube terminates, and the annular space is closed. It reappears again, however, on the top of the apparatus at A, where it is connected with the lower one by a spiral pipe o, o. A is provided with a cock h. If h is opened, the air escapes, and both annular spaces and the pipe o, o are filled with hot water. As soon as h is closed, the water in A sinks to a moderate temperature. The movable part of the apparatus is shown in Figs. 3, 4, and 5. It consists of two heavy copper wires d, d', terminating in a soapstone crucible k, k', which forms the bottom of a copper cylinder c', c'. The fusible alloy, in the form of a ring l', l', is inverted at the top of this cylinder, its temperature of fusion being so graded as to correspond with a certain pressure. A plug of soapstone v' covers the top of the cylinder c'. The upper ends of the wires perforate an apparatus exactly like the one just described (see Fig. 3), only that the point of fusion of the alloy is 100° C. The soapstone disks m, m' serve to insulate and strengthen the wires, which are made parts of an electric circuit. (See Fig. 1.) If we insert the apparatus, Fig. 5, in the tube i, i, so that the cylinder c', c' touches bottom, we find that the upper cylinder c, c is surrounded by the chamber A. Now, let the water-level sink below $L\,W$. Immediately the water column in the annular spaces drops out, and the chamber A is filled with steam of a temperature above 100° C. The ring l, l fuses, the alloy accumulates in the crucible k, k, closes the current, and all the alarm-bells in the circuit are sounded.

In case one of the dangerous conditions, given as the second, third, and fourth causes of explosions, exists, the alloy ring l', l', at the bottom of the tube i, i, is brought to fusion, and the result is the same as indicated before. Whenever an alarm sounds, the wires are taken out, examination made as to which crucible the alloy has fused, the latter poured out, and a new ring inserted. As soon as the boiler has been brought back to a normal condition, the wires are replaced. If several boilers are in operation, an annunciator with numbers is used.

Mr. Schwartzkopff recommends the Leclanché battery. As a matter of precaution, the efficiency of the battery and circuit is frequently tested by touching the two wires with a conductor. It is also well to open occasionally, for a few seconds, the cock h, to see if the spiral water-pipe is clear. The apparatus acts so quickly that the alarm

Digitized by Google

is given within a minute after one of the dangerous stages has been reached.

I will now give the results of investigations concerning several points of the apparatus. No difficulty is found in manufacturing the alloy rings with an accuracy of the desired fusion-point of ± 1° C. Those for the upper crucible are plainly marked with a W (water), and those for the lower one with the pressure corresponding to their fusing-point. It will be argued that, if the rings have been for a very long time in the apparatus, and have been heated so near their fusing-point, a degeneration of the metals might take place and their fusing-point become materially changed. This case was thoroughly tested at the Royal Artillery Works at Spandau, near Berlin. Rings which had been in the apparatus for eight months were taken out, and tested for their fusing-point in a paraffine bath. It was found that they fused at exactly the same temperature for which they were originally made. The question may be asked, whether the annular space of the apparatus does not get stopped up, in course of time, by boiler scales. This was also fully tested. An apparatus had been left uncleaned for eight months upon a boiler which was supplied with very hard water, requiring thorough cleaning every two months. An almost imperceptible coating only was found to have been formed. This is explained by the water stagnating in the annular space. Often repeated experiments have shown that a momentary freeing of the annular space—for instance, when by the boiling a wave depression is formed underneath it—does not empty it of all its water; in fact, the average lowest water-level must be reached before the steam reacts upon the upper alloy ring.

Finally, I will state, that in firing a boiler dry, rings for five atmospheres pressure, or 164° C. fusing-point, were fused when the lower sheets had reached a temperature of from 250° to 270°. Since a dark-red heat began at 500° C., the warning was given long before there was any danger of injuring the sheets by over-heating. Permit me to conclude this paper with Professor Reuleaux's opinion of this valuable invention, which he expressed in a meeting of the Gewerbeverein at Berlin. Professor Reuleaux said:

"I have been much interested to see Mr. Schwartzkopff's apparatus exhibited here. At his machine-shop, I have seen three boilers supplied with it, and convinced myself that it acts with precision. This apparatus has the great merit that it marks four dangerous conditions, namely, excessive pressure, low water, retarded boiling, and firing the boiler empty. That all this is possible, I consider of great importance, since the engineer has to keep in order only this one apparatus, which is very easy. The wires can be taken out at any time and examined. Besides, the whole apparatus is so simple, and can, as I suppose, be procured at such a moderate price, that it seems to me, we have to welcome in this invention a real progress in steam engineering.

THE TOTAL OUTPUT OF GOLD AND SILVER IN THE UNITED STATES.*

By Albert Williams, Jr.

It may seem strange to say that one of the most perplexing statistical questions is to state the total gold and silver production of the United States from the beginning of mining operations to the present. The difficulty lies not so much in the dearth of material as in the embarrassing abundance of statistics, actual and estimated, made by different persons at different times; covering overlapping periods and occasionally showing gaps; including and omitting the product of the Southern States; sometimes including the partial output of the west coast of North America beyond the limits of the United States; estimated on the basis of the calendar year or of the fiscal year; revised, changed, and corrected, until the whole subject seems lost in confusion. And yet there is sufficient reliable evidence upon which to reconstruct an estimate believed to have a probable error not exceeding five per cent.

First, we have Prof. J. D. Whitney's study of the gold output of the Southern States from 1804 to 1850, inclusive, showing the following results:

PROFESSOR WHITNEY'S ESTIMATE OF THE GOLD PRODUCTION OF THE SOUTHERN STATES FROM 1804 TO 1850, INCLUSIVE, BY PERIODS OF CALENDAR YEARS.

1804-23	$47,000
1824-30	715,000
1831-40	6,695,000
1841-50	7,715,300
Total	$15,172,300

PROFESSOR WHITNEY'S ESTIMATE OF THE PRODUCTION, BY STATES, DURING THE SAME TIME.

Georgia	$6,048,900
North Carolina	6,842,900
South Carolina	818,100
Tennessee and Alabama	263,800
Virginia	1,198,600
Total	15,172,300

This carries the history of production up to, and two and a half years later than, the discovery of gold in California. In the subsequent summary, a deduction has been made from Professor Whitney's total, in order to adjust these statistics to that most important date. From the $7,715,300 estimated for the decade 1841 to 1850, one quarter has been subtracted; thus reducing the estimate for the total production of the Southern States up to the turning-point in the output of the United States to $13,243,475. After the year 1850, the small production from this region has been usually disregarded altogether, until quite recently, when it again appears as an item in mining statistics. It is highly probable that during this intermediate period the total production of the country has been overestimated to an extent at least equal to the amount produced in the South.

Prof. W. P. Blake has carried the figures through the second natural time division (that is, the period during which California and Oregon may be considered to have been practically the sole producers) and up to the close of 1863, or somewhat beyond the proper limits of this epoch. The Comstock lode was discovered in 1859, began production in 1860, and by 1863 had made its influence largely felt. In 1863, prospectors were scouring Nevada, Idaho, and Washington Territory; and a considerable production began to come from other sources than California-Oregon, and the Comstock lode. Professor Blake's estimate of the actual gold exports from San Francisco, which has formed the basis for the figures now accepted, is as follows:

DECLARED EXPORTS OF GOLD FROM SAN FRANCISCO FROM 1848 TO 1863, INCLUSIVE, WITH ESTIMATES OF THE ACTUAL MOVEMENT, BY PROF. W. P. BLAKE.

YEAR.	Declared gold export.	Estimated actual gold export.	YEAR.	Declared gold export.	Estimated actual gold export.
1848	$66,000,000	$10,000,000	1857	$48,976,692	$55,000,000
1849		40,000,000	1858	47,548,026	50,000,000
1850		50,000,000	1859	47,640,462	50,000,000
1851 to May 1	11,497,000	55,000,000	1860	42,325,916	42,325,916
1851	34,960,895		1861	40,676,758	39,176,758
1852	45,779,000	60,000,000	1862	42,561,761	36,061,761
1853	54,965,000	65,000,000	1863	46,071,920	33,071,920
1854	52,045,633	60,000,000			
1855	45,161,731	55,000,000	Total	$676,908,228	$755,636,355
1856	50,697,434	55,000,000			

These figures do not show any silver production; in fact, silver mining in the United States may be said to have only begun in 1860. The value of the silver contents of gold, however, has been added in the compilations which are now generally accepted; and though the computation has been made in a very rough way, the value of the silver was so small as compared with that of the gold, that a revision seems hardly necessary.

Various authorities have been quoted for the period up to the time when a United States mining commissioner was appointed, and when Mr. Valentine began the publication of his estimates based upon the express returns. Mr. J. Ross Browne, in his reports as commissioner (1866 and 1867), gave the then accepted figures, which, however, were undoubtedly over-estimated, and they have since been materially reduced. Dr. R. W. Raymond, mining commissioner from 1868 to 1875 inclusive, made a very careful study of the subject, and his results, as published in his series of admirable reports, are generally accepted, though in a few cases over-estimates, which there was then no means of checking, could not be eliminated. The following table gives Dr. Raymond's estimates:

DR. R. W. RAYMOND'S ESTIMATE OF THE GOLD AND SILVER PRODUCT FROM 1868 TO 1875 INCLUSIVE (CALENDAR YEARS).

STATES AND TERRITORIES.	1868.	1869.	1870.	1871.
California	$22,000,000	$22,500,000	$25,000,000	$20,000,000
Nevada	14,000,000	14,000,000	16,000,000	22,500,000
Montana	15,000,000	9,000,000	9,100,000	8,050,000
Idaho	7,000,000	7,000,000	6,000,000	5,000,000
Oregon and Washington	4,000,000	3,000,000	3,000,000	2,500,000
Arizona	500,000	1,000,000	800,000	800,000
New Mexico	250,000	500,000	500,000	500,000
Colorado and Wyoming	3,250,000	4,000,000	3,775,000	4,763,000
Utah			1,300,000	2,300,000
From other parts	1,000,000	500,000	525,000	250,000
Total	$67,000,000	$61,500,000	66,000,000	$66,663,000

STATES AND TERRITORIES.	1872.	1873.	1874.	1875.
California	$19,049,098	$18,025,722	$20,300,531	$17,753,151
Nevada	25,548,801	35,254,507	35,452,233	40,478,369
Montana	6,068,339	5,187,047	3,844,702	3,573,600
Idaho	2,695,870	2,500,000	1,880,004	1,760,000
Oregon and Washington	2,000,000	1,585,784	763,605	1,246,978
Arizona	625,000	500,000	487,000	750,000
New Mexico	500,000	500,000	500,000	325,000
Colorado and Wyoming	4,761,465	4,070,263	5,188,510	5,302,810
Utah	2,445,284	3,778,200	3,911,601	3,137,688
From other parts	250,000	250,000	100,000	500,000
Total	63,943,857	71,651,523	72,428,206	74,817,596

Dr. Adolf Soetbeer (in Petermann's *Mittheilungen*, Ergänzungsheft No. 57) published conclusions reached by him as to the bullion product of the United States up to the close of 1875, based upon a study and comparison of the literature of the subject. In the following table, Dr. Soetbeer's results are shown, kilograms being converted into troy ounces and German marks into United States money. The production is given by periods of years:

DR. SOETBEER'S ESTIMATE OF THE PRODUCTION OF PRECIOUS METALS IN THE UNITED STATES TO THE CLOSE OF 1875.

PERIODS.	Number of years.	GOLD PRODUCT. Total.	Yearly average.	Value.	SILVER PRODUCT. Total.	Yearly average.	Value.
		Ounces.	Ounces.		Ounces.	Ounces.	
1804-20	17	1,929	113	$39,876			
1821-30	10	35,368	3,537	731,121			
1831-40	10	273,295	27,329	5,649,509			
1841-50	10	5,658,825	565,882	116,978,291			
1851-55	5	14,275,673	2,855,135	295,104,343	1,334,325	266,865	$1,725,149
1856-60	5	12,394,757	2,478,951	256,222,359	996,725	199,345	1,288,666
1861-65	5	10,722,862	2,144,566	221,660,603	27,972,602	5,594,520	36,165,777
1866-70	5	12,217,918	2,443,564	252,566,773	48,389,387	9,677,877	62,562,638
1871-75	5	9,565,344	1,913,069	197,733,203	90,798,425	18,159,685	117,383,284
Total	72	65,145,941	12,432,167	1,346,678,078	169,491,464	33,898,292	219,135,514

The figures which, partly by repeated official publication, are now most generally credited, are shown in the following table, which includes

* From advance-sheets of *The Mineral Resources of the United States*. Compiled by the United States Geological Survey Department of Industrial Statistics.

Digitized by Google

the estimates for the fiscal years from 1848 to 1880 inclusive. This table is made the basis of the second and most important item in the recapitulation, with the exception of the year 1880, for which the census figures are substituted:

ESTIMATE OF THE PRODUCTION OF GOLD AND SILVER FROM 1848 TO 1880 INCLUSIVE, BY FISCAL YEARS, AS GENERALLY ACCEPTED IN OFFICIAL REPORTS.

YEARS.	Gold.	Silver.	Total gold and silver.
1848	$10,000,000	.....	$10,000,000
1849	40,000,000	$50,000	40,050,000
1850	50,000,000	50,000	50,050,000
1851	55,000,000	50,000	55,050,000
1852	60,000,000	50,000	60,050,000
1853	65,000,000	50,000	65,050,000
1854	60,000,000	50,000	60,050,000
1855	55,000,000	50,000	55,050,000
1856	55,000,000	50,000	55,050,000
1857	55,000,000	50,000	55,050,000
1858	50,000,000	50,000	50,050,000
1859	50,000,000	100,000	50,100,000
1860	46,000,000	150,000	46,150,000
1861	43,000,000	2,000,000	45,000,000
1862	39,200,000	4,500,000	43,700,000
1863	40,000,000	8,500,000	48,500,000
1864	46,000,000	11,000,000	57,000,000
1865	53,225,000	11,250,000	64,475,000
1866	53,500,000	10,000,000	63,500,000
1867	51,725,000	13,500,000	65,225,000
1868	48,000,000	12,000,000	60,000,000
1869	49,500,000	12,000,000	61,500,000
1870	50,000,000	16,000,000	66,000,000
1871	43,000,000	23,000,000	66,000,000
1872	36,000,000	28,750,000	64,750,000
1873	36,000,000	35,750,000	71,750,000
1874	33,490,902	37,324,594	70,815,496
1875	33,467,856	31,727,560	65,195,416
1876	39,929,166	38,783,016	78,712,182
1877	46,897,390	39,793,573	86,690,963
1878	51,206,360	45,281,385	96,487,745
1879	38,899,858	40,812,132	79,711,990
1880	36,000,000	37,700,000	73,700,000
Total	$1,520,041,532	$460,422,260	$1,980,463,792

Statistics of the production are now, as they formerly were and always should have been, prepared for calendar years. For the six months from July 1st, 1880, to December 31st, 1880, half of the product of the fiscal year ended June 30th, 1881, as reported by the Director of the Mint, has been assumed. For the calendar years 1881 and 1882, the mint figures are again quoted. For the first six months of 1883, the estimate is made by assuming, on the authority of Mr. Preston, the rate of production in 1882 to have been maintained during the first half of 1883. It is not probable that the complete statistics for 1883 will show this estimate to be very seriously in error.

Summing up the material thus briefly sketched, the following results are reached:

PRODUCTION OF GOLD AND SILVER IN THE UNITED STATES TO JUNE 30TH, 1883.

PERIODS.	Gold.	Silver.	Total.
Output of the Southern States up to the discovery of gold in California in 1848 (based on estimates of Prof. J. D. Whitney)	$13,243,475	.....	$13,243,475
Product from 1848 to 1879 inclusive, by fiscal years (as published by the Directors of the Mint)	1,484,041,532	$422,722,260	1,906,763,792
Fiscal year ended June 30th, 1880 (census figures, covering a period one month earlier assumed	33,379,663	41,110,957	74,490,620
July 1st, 1880, to December 31st, 1880 (estimated on the basis of half the product of the fiscal year 1881, as reported by Hon. Horatio C. Burchard, Director of the Mint)	18,250,000	21,050,000	39,300,000
Calendar years 1881 and 1882 (as reported by Hon. Horatio C. Burchard, Director of the Mint)	67,200,000	89,800,000	157,000,000
Total product of the United States to close of 1882	1,616,114,670	574,683,217	2,190,797,887
Estimated product in the first six months of 1883	16,250,000	23,400,000	39,650,000
Total product of the United States to June 30th, 1883	1,632,364,670	598,083,218	2,230,447,887

Up to June 30th, 1883, the aggregate production of gold in the United States may be stated at $1,632,364,670, and of silver $598,083,217, making a grand total of $2,230,447,887. Reduced to the equivalent weights, the total gold output has been 78,965,572 troy ounces, or 2707·4 avoirdupois net tons. The total for silver represents 462,590,469 troy ounces, or 15,860 tons. It will perhaps convey little meaning to say that the grand total is in excess of the national debt; but a better conception of the vastness of the amount may be had by considering that all the gold produced in the country to the present time, if brought together, would suffice to load 271 ordinary freight-cars; the silver, supposed in the same way to be collected together as fine bullion, would require 1586 cars for its transportation. The gold would tax the carrying capacity of a large ocean steamship; while the silver would suffice to form cargoes for a small fleet.

Present Status of the Industry.—From the foregoing figures, the general deduction may be drawn that the annual precious metal output of the United States during recent years may be stated at between $70,000,000 and $80,000,000, coining value, and that the fluctuations in the proportional amounts of gold and silver are greater than those of the total product. It is also safe to assume that this rate of production will be maintained for some time to come, and that the probability of a slight increase is greater than that of a decline. Experience has shown that, as old districts become exhausted, or fall off in their rate of production, new localities are developed which fully take their place, and that the general result is therefore nearly uniform as compared year by year. By the time the country has been thoroughly explored for gold and silver deposits, a time which may be considered as indefinitely remote, the facilities for mining and working the ores will undoubtedly be such as to enable systematic and permanent development to be maintained in places and with ores which at present could not be profitable. The production of the precious metals appears to be the sole industry which is at all independent of changes in the relation between supply and demand, unless, indeed, the influence exerted by fluctuations in the market value of silver may be held to affect the production of that metal. With all other natural products, the amount produced is necessarily limited by the amount consumed, whether in this or in foreign countries; notable examples of which effect may be seen in the case of quicksilver, which, at a certain demand and consequent market value, may be mined profitably, while, if the price declines only a few cents per pound, a number of mines are at once thrown out of operation, and the production falls off until an equilibrium is reached at which resumption of work is profitable. In the case of the great iron industry, in which, as is so often seen, over-production brings its own remedy, and as is found to be true in other almost innumerable instances which might be cited, it would require very violent changes in the purchasing power of the precious metals to materially affect the rate of their production. It might even be said that the latter is apt to increase in cumulative ratio; for unusual success in any locality at once attracts attention and stimulates prospecting for new deposits and their exploitation, the ultimate result being a sympathetic increase throughout the mining region. But while natural causes are thus seen to influence the rate of production only slightly, artificial restraints, such as the crusade against hydraulic mining in California or the adoption of unwise laws, certainly make their influence felt, although for the country at large the effect is relatively small. In like manner, the reaction from undue speculation has a slight depressing result, which shows itself in apparently returning cycles. Sudden changes in the normal supply of either of the precious metals bring about from time to time corresponding changes in the coinage laws of nations; the reflex action upon production, however, is hardly more than perceptible.

The production of gold and silver, like that of other commodities, is of course not one of clear profit. Indeed, a saying that it costs one dollar in coin to produce one dollar in bullion has gained more or less credit; and though this opinion has been abundantly shown to be unfounded, and while also any attempt to estimate the profit gained to the country by the mining of the precious metals is mere guess-work, it is still quite probable that $500,000,000 of the gross total has been net profit.

One third of all the gold and one half of all the silver annually produced in the world are supplied by the mines of the United States.

THE SMALLEST LOCOMOTIVE.—The *Railway World* says that the smallest locomotive engine ever built in the United States for regular work was turned out by M. M. Duck & Co., of St. Louis, recently, and shipped to the Edmee plantation, St. Charles Parish, La. This little engine was designed by and built under the supervision of Mr. Jay Noble, and is as perfect a piece of mechanism as one would wish to see. Its diminutiveness may be understood from the following facts respecting it: Twenty-one and one half inch gauge; diameter of cylinder, 6½ inches; stroke, 10 inches; four wheels, diameter of driving-wheels, 24 inches; height of engine to top of boiler, 4 feet 7 inches; weight without water, 5250 pounds. The engine has link motion, and is made of the best materials throughout. The boiler is made of ¼-inch iron, and is 30 inches in diameter in the barrel. It is provided with an Orm patent pop-valve, has a steel fire-box, and is fed by two inspirators. The tank is made of No. 10 iron, has four wheels of a diameter of 16 inches, a capacity of 380 gallons, and weighs, without water, 1400 pounds. In experimenting with the engine before it was shipped, it was found to act very obediently under the hand of the engineer.

FURNACE, MILL, AND FACTORY.

The Gates Iron-Works, Chicago, are about starting a crusher at Haythorne station on the Chicago, Burlington & Quincy Railroad. It is one of their largest sizes, will take rock 16 by 24 inches, and has a capacity of six hundred tons per day of ten hours. They have also just started one of their No. 6 machines at South Bethlehem, N. Y. The latter machine is crushing rock for railroad ballast.

The Chicago Smelting and Refining Company, at Chicago, has rebuilt its works, which were burnt last winter, and is now treating about fifteen tons of bullion a day. It expects to have the whole plant in thorough running order in about one month, and its capacity will then be eighty tons daily.

The Topton Furnace, Berks County, Pa., which had been idle for some time, will go into blast at an early day, in consequence of the recent explosion at Kutztown furnace. William M. Kaufman & Co., of Reading, are the lessees of both furnaces.

It is stated that the material of the Princess furnace, at Ashland, Ky., exclusive of ore, has been sold for $10,000 to parties who will remove it to a few miles beyond Lowmoor, Va., where it will be set up again for the manufacture of iron.

The Steelton *Reporter* says of the work of the Pennsylvania Steel Company: The product of the Bessemer mill for the month of July was 1895 blows, producing 13,913 tons of steel ingots. The product in turns is as follows:

A turn	628 blows	4596 tons.
B turn	641 blows	4704 tons.
C turn	626 blows	4617 tons.

The rail-mill for the month of July produced 40,158 rails or 9609 tons of steel rails. During the month, six changes of rolls were made, and a loss in running time of four and a half days, occasioned by shutting down the works for the usual Fourth of July holiday. The blast-furnaces have made a good showing for the year ended July 30th. No. 1 furnace produced in eleven months 14,246 tons of pig-iron. This furnace went out of blast a month ago, and is undergoing extensive repairs and improvements, which will increase its capacity. No. 2 furnace produced 42,785 tons during the year, and is in successful operation. No. 2 shows an increase of 5500 tons over the preceding year. The product of No. 2 furnace for July was 4052 tons, and that of No. 5 furnace 450 tons. No. 5 was not in blast during the full month. The first smoke from the big stack of No. 3 issued forth on Wednesday, occasioned by fires being kindled for the purpose of drying out the stoves.

The Tyrone Iron Manufacturing Company, Tyrone, Pa., has decided to erect furnaces, rolling-mills, and machine-shops there.

The Nashville Merrill Pump Company has been duly chartered. The company

Digitized by Google

organized by electing T. A. Atchison, A. S. Colyar, A. J. Grigsby, J. N. Brooks, Baxter Smith, and W. M. Duncan, directors. They elected A. S. Colyar, President; J. N. Brooks, Vice-President; A. J. Grigsby, Secretary and Treasurer; and M. Merrill, Superintendent. They have already commenced building a manufactory near the city limits, on the Northwestern Railroad, and will be fully at work this fall.

The new iron-works in course of erection at Thirty-fourth and Wyncoop streets, Denver, Colo., are nearly completed. The building will be ready to receive the roof in a few days, and the work is prosecuted with great industry. It is hoped to have the works completed and in running order by the early days in September. The works when completed, will give employment to about seventy-five men.

Annin & Co., Water street, Brooklyn, N. Y., are fitting out a complete equipment of machinery for the manufacture of iron wheel-barrows and steel hand-trucks.

Wilson, Snyder & Co. have just sold to Jones & Laughlins one of their large plunger pumps, with 24-inch steam cylinder, 20-inch plunger, and 48-inch stroke. It is to be used in supplying the American Iron-Works with water.

The Watt Mining Car-Wheel Company, Barnesville, Ohio, is driving things along at a lively rate. Its machinery—trip-hammer, furnace, boring-machines, drill-presses, etc.—is all specially adapted to the manufacture of its specialty, Watt's patent self-oiling mine car-wheel. It works from twenty-five to thirty men at all times, and is always crowded with orders. Its trade extends to nearly every mining region in the United States.

Palmer, Mass., expects to have a wire-cloth manufactory located there, by Worcester parties, provided the citizens subscribe $1500 toward the enterprise.

The Gulf Shot and Lead Company's tower, at New Orleans, La., is now up to the hight of ninety feet, and will be, when completed, 200 feet high. It is composed of wrought-iron legs tied together with braces and built in with brick.

The Pennsylvania Combustion Attachment Company has been incorporated in Philadelphia, to make and apply the Orvis combustion attachment and smoke-consumer to steam-boiler furnaces. R. B. Swain is President; John S. Stevens, Treasurer; Charles Perkes, Secretary; and L. B. Eaton, General Agent. Capital stock, $100,000.

The South Tredegar Iron-Works, of Chattanooga, Tenn., have decided to introduce Swedish labor altogether in certain departments of their mill. Seven of these Swedes have arrived, and several more will arrive shortly.

Joseph Radcliffe writes the American *Machinist* from Glen Rock, Pa., that an effort is now making to organize a stock company in that town, with a capital of $40,000, to manufacture steam-engines, boilers, and agricultural machinery. Of the amount, $35,000 are subscribed. It is proposed to transfer to the new company the car and machine-shops of Fry, Herbst & Co., for $18,000, this amount to be taken in stock.

The Marshall Foundry and Machine Company, Marshall, Tex., is preparing to erect a new wheel foundry and other buildings. The wheel foundry will be 75 feet wide and 115 feet long. The walls will be 20 feet high, with a lantern roof 40 feet above grade. The new foundry will enable the company to increase its present capacity of 10,000 per annum to over 40,000. The company is far behind its orders, but hopes to have its new buildings in working condition very soon, when it will be in shape for any reasonable amount of new work. The company has just finished a liberal order for stock and coal-cars for the International & Great Northern Railroad, and is now working on an order for coal-cars or gondolas for the Texas & Pacific Company,

C. H. Parmalee, of Dadeville, Ala., is putting a Westinghouse engine into his stamp-mill.

The Kelly Smelting Company, of Socorro, New Mexico, will run its fans and crushers by two Westinghouse engines of 30 horse-power each.

The Tucson Electric Light Company, of Tucson, Arizona, has recently started its new lighting station. Its plant consists of a 40 and a 16-light Brush machine, driven by a 60 horse-power Westinghouse automatic engine.

The Council Bluffs Water-Works will pump the muddy water of the river into their settling-basins by two 15-inch Andrews centrifugal pumps. Each pump is coupled directly to a Westinghouse engine of 100 horse-power, making 300 revolutions a minute, and fitted with an adjustable cut-off, in order that the speed may be varied to meet the varying hights of lift.

The New York, West Shore & Buffalo Railroad is driving the power in its new shops in a novel and effective manner. Instead of belting from the engine to the line-shaft in the usual manner, each shaft is driven by an independent engine, coupled directly to it. To effect this, the arched door-way in the central brick partition is strengthened by piers, and a second arched opening left over it similar to a transom. The floor of this opening forms the foundation for a Westinghouse engine, which is set with its centers exactly in line with the shafting, to which it is coupled on each end. No regular engineer is employed; but the engine is considered a part of the shafting and is in charge of the wiper. The Westinghouse Machine Company has so far fitted up the shops at New Durham, N. J., with a 12 by 12; at Kingston and Syracuse, N. Y., each with a 9 by 9; and at Schenectady with a 7 by 7 engine.

The Omaha Smelting and Refining Company, of Omaha, and the Grant Smelting Company, of Denver, have been consolidated, and hereafter will be known as the Omaha & Grant Smelting and Refining Company, and will have offices at Omaha, Denver, and Leadville. The refining-works at Omaha are running on full-time, day and night, employing about 300 men, and are capable of treating 130 tons of bullion a day. Their total product for 1882 was: Silver, $5,339,236.67; gold, $805,440; lead, 43,711,921 pounds; bluestone, 1,152,041 pounds. The total value of their product for the first three months of this year show a very satisfactory increase, amounting to $1,167,269.61 more than the same period in 1882.

GENERAL MINING NEWS.

ARIZONA.

PINAL COUNTY.

AUSTRALIA.—Work has been resumed.

EUREKA.—Work continues and the mill is abundantly supplied with ore from that mine. Fifteen men are employed in the mine.

MONARCH OF THE SEA.—The working-force has been greatly enlarged. A double-compartment shaft is sinking, and several feeders of rich ore from the main vein have been cut. Several drifts are worked, and good ore is taken out.

SILVER KING.—Owing to the lack of water, the mill has stopped running. The Pinal *Drill*, provoked at the San Francisco's *Bulletin's* statement that, from the further decline of the stock, it was evident that dividends were to be suspended, says: The Silver King may be weak on the stock board, and who cares? The Silver King is stronger than ever in the earth, and the company employs more men than ever, and has more rich ore than it can handle. It pays its men who work at the mill and mine. The company will have to build a 100-stamp mill at once or be choked with ore, and it is probably saving its dividends for that purpose.

SURPRISER.—Four drifts have been opened, and gold quartz has been found.

YAVAPAI COUNTY.

UNITED VERDE COPPER COMPANY.—The smelter made its first run August 2d, turning out a bar of fine copper bullion. It was the intention to keep the smelter running, but the present impassable condition of the roads will delay the transportation of coke, etc., and necessitate a suspension, which will be of short duration, however.

CALIFORNIA.

AMADOR COUNTY.

PLYMOUTH CONSOLIDATED.—The Amador, Pacific, Empire, and Plymouth mines at Plymouth, Amador County, have recently been consolidated under a single corporation, known by the above name, with a capital of $10,000,000, in 10,000 shares. The company owns two mills, 40 and 80 stamps respectively, and is well equipped with Frue concentrators. The mines are thoroughly opened with three shafts, the last one constructed being vertical, 1400 feet in depth, in three compartments, and thoroughly timbered. The rock is a ribbon quartz, varying from $12 to $16 per ton.

MONO COUNTY—BODIE DISTRICT.

There is nothing of interest to report from the mines of this district. Work goes on as usual.

CANADA.

PROVINCE OF MANITOBA.

ARGYLE.—In point of organization, this company was the first on the Lake of the Woods, and was begun in August last. The machinery which has been erected is only temporary, and consists of stamps and Frue vanners of Fraser & Chalmers's manufacture.

LAKE OF THE WOODS.—Work will begin shortly on this company's property.

MAIDEN.—This mine has a four-foot vein carrying a heavy mineralized quartz, in which free gold shows itself.

MANITOBA CONSOLIDATED.—Alongside of the Argyle, this company is sinking upon what it believes to be the Argyle lead; but whether it is so or not, it can strike either lead by a cross-cut under the lake.

MINNESABIC.—Two shafts are sinking on this property. The ore is said to be of the same character as that of the Maiden.

RED STAR.—According to the Chicago *Mining Review*, this mine has a vein measuring over 40 feet on the face, as now uncovered, and swelling at points to 80 feet, in its course across the island. The quartz is white, and is richly impregnated with copper pyrites. Assays made show the pyrites to contain 23⅞ per cent of copper and $118.93 in gold. The George Heenan Company is reported to have acquired some kind of ownership.

WINNIPEG CONSOLIDATED.—After a series of experiments that will likely be supplemented by kiln-roasting, the permanent character of the machinery will be decided upon. The shaft is down 114 feet, and the vein, which began with only four inches on the surface, has widened out to over six feet. The pay-streak is decomposed and over two feet wide. It shows fine gold, and is streaked with carbonates of copper. The gangue is worth about $10 a ton. There are seven or eight veins, all of them showing fine mineral.

NOVA SCOTIA.

The Sherbrooke *Gazette*, speaking of the progress of the construction of the Sherbrooke & Magog Railroad says: This road, when completed, will furnish an important auxiliary to our mining industries, which should not be overlooked in estimating the advantages it will confer upon this section of the Eastern Townships. It is the intention to construct a branch line to the mining properties already developed, known as the Suffield copper and silver mines, and the Hepburn copper and sulphur mine, which branch will also run close by Mr. Clark's rich iron mountain. The ore from these mines can thus be taken by rail to the smelting-works on the main line, or find a direct outlet to New York down the Hudson River Valley.

COXHEATH.—Operations are said to be proceeding with most efficient regularity and system, and, though a new enterprise, the results are already exceedingly gratifying, and are apparently certain to become still more so in the immediate future.

ONTARIO.

Several New York gentlemen are reported to be exploring the mineral districts of the Gatineau just across the Ottawa River from Ottawa. Their ostensible object is the phosphate mining lands, but it is said a search for gold and silver also occupies their attention to a great extent. Work is still pushed forward vigorously in phosphate mining, notwithstanding the somewhat dull state of the market.

COLORADO.

ARAPAHOE COUNTY.

HARRIS MANUFACTURING AND MILLING COMPANY.—This new amalgamating concern will be in working order shortly.

GRANT SMELTER.—To the north of the smelter, and in the rear of the office, a three-muffle assay-office has been erected. It is similar to that now in use at the Argo works. The furnace has been completed, and will be worked at once. In addition to the furnace, a large sampling-works, 100 by 40 feet, is in course of construction. Heretofore, the Grant smelter has done no sampling of ore. All the work of this kind has been done at Leadville, at the Denver sampling-works, and at the Colorado ore sampling-works. The new sampling-works will do away with this, and hereafter the Grant smelter will do its own smelting. The crushers have not arrived as yet. An important improvement will be the new furnace for roasting matte, which is now going up.

CLEAR CREEK COUNTY.

SEVEN-THIRTY.—Five levels are pushed ahead, three of which are mineral. A winze 200 feet east of the main shaft is sinking on a fine streak of smelting ore, which runs from 500 to 400 ounces per ton. The 310-foot level east continues in a large streak of smelting ore, heavy in lead but comparatively low in silver. The 375-foot level west is driven in barren ground; but on the west side of the main shaft at this point, there is a fair streak of smelting ore. Somewhat over $6000 worth of ore was shipped last month.

DOLORES COUNTY.

CROSS.—A strike has been made, showing eight inches of mineral in a vein uncovered for 250 feet, running 900 ounces of silver and 30 per cent lead. This property adjoins the Grand View group.

FREMONT COUNTY.

ROCKY MOUNTAIN MINE DEVELOPMENT COMPANY.—One car-load of machinery for the copper smelter has been shipped from Chicago. The plant will be situated a few rods east of the Royal Gorge smelter.

GUNNISON COUNTY.

A dispatch from Gunnison City says that Mr. John Crooke, of the Lake City smelter, and B. W. Lewis, of St. Louis, have been in close consultation for two or three days, and have privately decided to locate a smelter in Gunnison.

GUNNISON ORE-SAMPLING COMPANY.—This company has just been organized. The establishing of these works will be of great importance not only to the steady

Digitized by Google

producers of the country, but also to the proprietors, as it will enable the latter to dispose of their small lots of ore and give them the means whereby to develop their properties. The exact site of the mill is not yet fully determined on, but will be either in the town of Pitkin or at Quartz, three miles from Pitkin. Quartz is the present shipping-point of the Tin Cup and Pitkin.

HINSDALE COUNTY.

The success attending the Crooke concentrator, says the Lake City *Silver World*, has added new interest to this industry. Plants have been started all around the country; more are coming, and another year will see them at every mine of ordinary development.

The new Pittsburg concentrator, at Mineral Point, will be started up shortly. The work has been pushed with great energy.

The machinery for the Henson Creek Reduction Company's concentrator has arrived. The active work of putting it in position will be commenced at once.

LAKE COUNTY.

The *Herald's* description of the mines on Rock Hill shows that the western portion, from the Stone and Dome mines to the Columbia property, is showing up very well, and gives indication of a large production in the near future. Even at the present time, this section is producing over one hundred tons of fine smelting ore a week, derived largely in prosecuting the exploration of the territory and the development of the mines.

The Vining is one of the most regular producers of the section, having averaged for a year past about thirty tons a week.

Just below the Vining, is the Oro City mine, a comparatively new property, having begun regular shipments but about a month ago. This week, the product of the Oro City will aggregate at least forty tons, with a large prospective increase in a very few weeks. The yield of the mine is a fine carbonate ore, carrying from thirty to fifty per cent in lead and from twelve to twenty-five ounces in silver to the ton.

Just below and west of the Oro City, is the O'Sullivan shaft. During the present week, exploration-work from this shaft has encountered indications which leave little doubt but that it will soon possess the same ore-body that is now supplying the Ben Burb mine with its large production. The O'Sullivan has been working for a year past without a day's intermission, and among its underground workings contains a drift four hundred feet in length.

The Ben Burb mine, of the Robert Emmet Consolidation, is also meeting all expectations, and is doing fully as well as any of the adjoining mines. The ore, like that of the neighboring properties, is a fine carbonate of lead mineral. The contact so productive in the Oro City and Ben Burb loads is regular, showing a good lime floor and even cap of porphyry. It continues without interruption to the Columbia tunnel, where a fault produces a displacement, and depresses it to the westward to a depth that has not yet been attained by any of the shafts sunk on that portion of the hill. Between the Ben Burb and Columbia is the Robert Emmet, the most western property working and producing. It is the principal property of the Robert Emmet Mining Company, and has produced in limited quantities quite steadily for several years past. With the settlement of the pending litigation over these properties, it is reasonable to expect the development of very extensive resources and quite a large ore production.

The County Commissioners have granted J. S. Delan the privilege of constructing a railroad or tramway along the county road through California Gulch to Oro. The new enterprise is intended to expedite the production of the carbonate mines on the Iron and other hills sloping into the gulch. The road, which promises to reduce charges for ore hauling, will be constructed at an early day.

ADLAIDE.—A large body of ore was struck in the 360-foot level. Tests made show eighty ounces of silver and one ounce of gold to the ton. The ore also carries from ten to thirty per cent in lead. Considerable exploration-work had been done from this shaft two or three years ago, on the 167-foot level, but failed to show any extended or high-grade ore-bodies.

HAMBURG CONSOLIDATED.—This company's properties, situated on Breece Hill and adjoining the Highland Chief mine, have been leased. The developments of the property consist of a shaft down 365 feet. At about one hundred feet from the surface, the shaft passed through the contact, and the parties now working, being cognizant of this fact, started a drift at ninety feet and soon encountered the vein, which had all along escaped detection.

HIGHLAND CHIEF.—This property, which has been worked under a lease for a year or more past, is reported as falling off in the tonnage of its production as well as the grade of the ore. For some months past, the company has not realized any royalty from its lessee, and the prospects now are, that at the expiration of the present lease, which will be August 31st, it will be impossible to renew the lease on present terms.

MCCLELLAN.—The mill has been closed down.

ROBERT E. LEE.—It is stated, on what authority is not known, that an analysis made of the water pumped from the Robert E. Lee shaft shows a large amount of silver carried in solution.

ROSEVILLE-ALTA.—The new shaft, while encountering considerable water, has by no means the strong flow to contend with that was met in the old shaft, the latter now being filled to within fifty feet of the surface. The absence of the ore at the present depth is accounted for on the theory that there is a fault or displacement of the formation between the two shafts. The formation passed through in the new shaft is as follows: Boulder wash, 122 feet; porphyry, 12 feet; lime, quartzites, and shales, 72 feet; porphyry, 4 feet; total depth, 210 feet.

SMUGGLER.—This property, situated on the southwest side of Iron Hill, hemmed in by the Iron Silver, Silver Cord, and Iron Hill Consolidated mines, is a small piece of territory which for some months past has produced regularly. The company has now about twenty thousand dollars on hand.

YANKEE & BREECE HILL CONSOLIDATED.—The Loveland lode has been leased. The shaft was sunk some years ago, and passed within eighteen inches of a fair streak of ore. This has been followed by the present lessees until, at a distance of thirteen feet from the shaft, it opened out into quite a body of thirteen-dollar ore. In connection with it is a streak four inches in thickness, running nineteen dollars to the ton.

SUMMIT COUNTY.

GOLD PLACER.—The Leadville *Democrat* reports the sale of this company's placer property, in order to satisfy promissory notes given by the company to Mr. C. G. Hathaway in September last. The property was bid in by Mr. Hathaway for $8971, being the amount of the notes running to him and the accrued costs. A want of concert of action on the part of stockholders in the company was the cause of the failure to raise the money. The property is situated near the confluence of the Blue and Swan rivers. There are 800 acres of placer lands, to which good title is held, the greater part of that amount being patented, and an immense acreage on all sides is valuable only to this company, as it controls the water, and in an emergency can empty all the water of both the rivers mentioned into its flumes. Something over $70,000 have been spent in opening the placer, and only a small sum is now required to place it on a basis of large production.

ROBINSON.—The terms of the new lease secured by Mr. Greer for eight months are as follows: The lessee agrees to pay the company the following royalties: On ore under 35 ounces to the ton, three dollars per ton; ore of 35 ounces and not exceeding 40, four dollars per ton; ore of 40 ounces and not exceeding 45, six dollars per ton; ore of 45 ounces and not exceeding 50, nine dollars per ton; ore of 50 ounces and not exceeding 55, twelve dollars per ton; ore of 55 ounces and not exceeding 60, eighteen dollars per ton; on all ores over sixty ounces, in the proportion of eighteen dollars per ton per sixty ounces. Settlements are to be made with the company on the first of every month. The lessee agrees to employ not less than sixty-five men, and extract at least fifteen hundred tons a month, provided the ore is contained in the mine and available. He also agrees to diligently prosecute development-work on the line of the ore-chutes below the thirteenth level, and keep development-work at least fifty feet ahead of the extraction of the ore. He moreover agrees not to mix the ores to deteriorate the grade of the mineral shipped, nor to permit any indebtedness or encumbrance to accrue for which the property may become liable. The lease is accompanied by a bond signed by Messrs. W. B. Scott and William H. McCraig, insuring the company against any possible damage. During the past four months, under Mr. Greer's administration, the mine produced and shipped 3350 tons of ore. The output of the mine was shipped principally to Argo, except some of the oxidized ores, for which a better market is offered in Leadville, and which were in consequence sent to the Arkansas Valley smelter. The ore is reported to average from thirty-eight to forty-two ounces to the ton.

WHITE QUAIL.—Late last week, the sheriff again levied on this property, says the Ten Mile *News*, for a debt of some $300 due to Dan Recen. The sheriff attached the hoister at the mine and some machinery at the old smelter. This claim will have to be adjusted before the mine can resume work under the lease.

DAKOTA.

CALEDONIA.—The superintendent reports for the week ended August 5th: Ore produced, from 300-foot level, 966 tons; 400-foot level, 84 tons. Shipped, 553 ounces gold; value about $9500. The 400-foot level header has advanced four feet, making a total of twenty feet. The ore in this header is looking very well.

DEADWOOD.—This hydraulic company has shut down, owing to the scarcity of water, and is now engaged cleaning up. Although many drawbacks have been experienced, the result of the short season's work is satisfactory.

FATHER DE SMET.—The superintendent's report, from July 31st to August 8th, shows ore extracted from first, second, and third levels, 2025 tons. Ore milled, 2025 tons. Golden Gate cross-cut 3d level advanced 6 feet. Total, 25 feet. Work stopped. Golden Gate south header advanced 7 feet.

GOLDEN SUMMIT.—The mill is running constantly.

PORTLAND.—A number of men were discharged by this company recently, and the probabilities are, that the mill soon be idle, all owing to lack of water. No extensive operations can be inaugurated by the Portland until new works are erected on Spearfish, or a water supply secured from some source.

RICHMOND *vs.* SITTING BULL.—Action has been commenced by the Richmond company against Colonel Davey, to enjoin the latter from working the Sitting Bull, on the ground of trespass. It is stated that the Richmond sank to a depth of 138 feet without striking any thing of value, whereupon a drift was run tapping the ore-body of the Sitting Bull, on the dip.

WELCOME.—Seventeen miners in the employ of this company struck recently for an increase of pay to $3.50 per day. Their demands were not complied with, and they packed up and went to Deadwood. Not over one half of the machinery for the new works has arrived; carpenters have not begun work on the mill building; and it will be at least two months before the reduction-works will be ready for operation.

FLORIDA.

We are informed that deposits of magnitude of hematite, running 0·22 per cent of phosphorus and 51 per cent of iron, have been discovered by Mr. Albert Hill, C.E., in Northern Florida.

Extensive phosphate-beds, similar to those of South Carolina, have been discovered in Florida, and a scientific examination has been so favorable that the Ashley Phosphate Company, of Charleston, S. C., has already purchased 3000 acres of land covering these beds, with the view of erecting extensive works at Charlotte harbor.

GEORGIA.

The news from the mines this week, says the Dahlonega *Signal*, is not of the most cheerful nature. The drought still continues, and mining operations, except in a few favored localities, are consequently almost suspended. Many individual operators who have been working small placers now find themselves nearly or quite deprived of that absolute necessity, water. The mining companies operating here are as a rule running their works at about one half capacity. Notwithstanding this condition of things, those mines now worked are yielding fair returns, and but few, if any, find the proceeds from sale of bullion more than counterbalanced by mining and expense account.

IDAHO.

PHILADELPHIA MINING AND SMELTING COMPANY.—According to the Wood River *Times*, a contract has been made with the Union Pacific and Oregon Short Line companies, according to the terms of which the smelting company agrees to import from Rawlins, Wyoming, or Tintic, Utah, all the iron ore which the smelting company will require for flux. As the capacity of the company's works is 180 tons of ore per day, the company is liable to require as much as 5400 tons of iron per month, or five hundred and forty car-loads. The company has felt compelled to go outside for flux, because of an attempt, on the part of local owners of iron mines, to "corner" the smelting company and make it pay more than it considered the East Fork iron ore worth. The company has, from the start, been buying iron ore from three mines on the East Fork of Wood River; but recently a Mr. Burton, who claims to be operating here for a company in which Senator Tabor, the Colorado millionaire, is a stockholder, secured the control of two of the mines, and E. S. Chase secured the other by exchanging his interest in the Star group for it; and they at once raised the price of the ore on the Philadelphia Company, with the result above stated.

SILVER KING.—The mine has been sold for $125,000. The purchasers propose to work the property vigorously. They will at once begin shipping ore to the Sawtooth and Vienna mills. The mine is located on the head of Beaver Creek, and receives the water-shed of both sides of Beaver Cañon. The workings are filled with water up to within 35 feet of the surface. Above that level, careful estimates show 200 tons of ore in sight, averaging $200 per ton.

MAINE.

DOUGLASS.—Since the first of June, the company is reported to have shipped and sold in the Boston market 59,000 pounds of refined copper, for which the average price realized was 14⅝ cents per pound. The July product of the works aggregates about 75,000 pounds.

TRENTON FLINT AND SPAR COMPANY.—This company is operating a feldspar mine, located on the farm of Mr. Austin, at Topsham. It has a mill on the Cathance River, about a third of a mile from the railroad, where the spar is crushed. The mine is distant about a mile and a half from the mill, to which the mineral is transported in coarse lumps, by teams. Arriving at the mill, the spar passes through crushers and comes out a powder finer than the finest flour. Three car-loads of the crushed spar, amounting to 36 tons, are shipped each week, and it is used almost exclusively for the manufacture of the finest crockery and porcelain ware. The Maine Central has built a spur track for the accommodation of the company, thereby greatly lessening the distance between the mill and the cars.

Digitized by Google

MEXICO.

The Governor of Chihuahua, in a recent interview with a correspondent of the New York *Tribune*, said: It is a mistake to suppose that the laws of this country are illiberal to mining. A few years ago, there was a tax of 42¼ cents on every half-ounce of silver metal; now that tax is repealed. Every $100,000 invested in a mine, or by one company in several mines, is exempt from tax for six years.

ANGLO-MEXICAN.—The copper mines recently denounced by this company in the district of Zimapan are turning out to be very rich. A tract of 90,000 square meters has lately been denounced by the company for the establishment of reduction-works.

MICHIGAN.

The following statements show the yield (in mineral) of each of the reporting mines of Portage Lake and Keweenaw districts for the month ended July 31st, 1883, and the total product for six months:

	July.		Total.	
	Tons.	Lbs.	Tons.	Lbs.
Calumet & Hecla	1,657	1,770	11,783	285
Quincy	300	495	1,657	785
Atlantic	158	660	1,116	654
Franklin	179	975	1,141	1,190
Allouez	111	710	687	920
Pewabic	64	500	476	1175
Peninsula	42	845	340	445
Grand Portage	38	...	255	1,024
Hancock	58	....	275	1,317
Wolverine	....	....	205	1,295
Phœnix	....	....	200	1,700
Copper Falls	....	....	297	885
Grand total			18,437	1655

CABIRA.—Considerable exploring is done by the management on its track in section 16, 42-32. A churn-drill is now at work 35 feet east of the main shaft, and is down 30 feet. The object of this work is to ascertain if the ore-body widens going in that direction, the dip in the bottom of the shaft being to the east, and at an angle leading to the belief that the drill-hole will strike it at a depth of about 40 feet. A shaft will also be put down shortly some 40 feet west and a little north of the present working, where it is confidently expected that a workable deposit will be found.

EMMETT.—It is stated that the exploration of the company's property, adjoining the Ludington, has been abandoned.

FRANKLIN.—The arrangement for delivering coal from the lake front at the chief point for consumption at this mine on top of the hill is a very complete one. Cars filled at the lake are run up over the incline by automatic power, on to the main track, and landed by the locomotive at the entrance of the fuel-chamber, and unloaded on trestle-work in front of the boilers by a self-acting dump.

GREEN MINING AND EXPLORING COMPANY.—This company has been formed at l'Anse for the developing of lands in the vicinity of Michigamme. Operations will be commenced on section 31, town 48, range 30. Good indications have been found on this property by former explorations, and much is expected as the result of work about to be prosecuted.

HURON.—The new stamp-mill of this mine has been in operation several days, and is giving satisfaction.

HYDRAULIC POWER COMPANY.—Most of the pipe for conveying the compressed air from its plant of air-compressing machinery at the Little Quinnisec Falls to the Chapin and Ludington mines, near Iron Mountain, is on the ground. They will shortly begin setting the pipe line in position. The air-compressors are now getting into place.

OSCEOLA.—The annex to be placed on the west side of the dressing-works for the new head of stamps is now in course of construction, and will be ready in a short time for the machinery.

REPUBLIC.—The result of the recent strike is the restoration of the scale of wages in effect prior to the first of June last.

MISSOURI.

Reports from Rich Hill state that the oil excitement continues. Lands are bought at fabulous prices. Thousands of acres are leased, and options taken for thousands of acres more, and many large and small tracts have been purchased at from $50 to $100 that a month ago could have been bought for $20 to $40. Several gas-wells have been found, and more oil-wells. Oil-rock abounds over a considerable territory, and the extent is unknown. The number of wells under contract continues increasing, and machinery is shipped from Chicago and Pennsylvania.

MONTANA.

AMAZON.—A shaft, 176 feet deep, has been sunk on this property, with two levels running east and west. The width of the vein is 16 feet. The lower east level is 75 feet in length, and the west level 80 feet. The width of the vein at this point is 26 feet. The assays from the lower level will average 80 ounces in silver. Steam hoisting-works have been put in position, and a large amount of ore is taken out daily. About two miles from the mine, the company is putting up concentration-works. The smelter will have a capacity of 30 tons. The stamp-mill has two batteries of 10 stamps each, with a capacity of 40 tons daily. The length of the flue from the smelter to the stack is 250 feet, the hight of the stack is 40 feet. The works will be in good running order by the first of October.

BOULDER.—During the past three months, this mine has been worked under a lease, and has paid well. Some of the ore worked ran as high as $40 per ton in gold saved in the mill, and still the principal value of the mine product is in silver. The lease expired on the 1st inst., and the corporation now contemplates changing its present mill so as to enable it to save the silver. At present, it only saves gold, and the excess of silver renders it difficult to save more than a small percentage of that.

DRUM LUMMON.—The London purchasing syndicate has ordered a mill from Messrs. Prescott, Scott & Co., of San Francisco.

MISSOULA COUNTY.

PLEASANT VIEW.—The Bitter Root quartz, about which the people have been hearing for the past two years, says a correspondent of the Butte *Miner*, is still in such a condition that it is not now known that more than one mine exists in the region where the rich quartz has been found. Hon. H. E. Bass bought and leased interests until he obtained control of a location called the Pleasant View. A shaft has been sunk to a depth of 125 feet on the vein. Levels were run out at fifty and one hundred feet, to ascertain the character and extent of the ore. The ledge has a uniform width of four or five feet. There are about 200 tons of ore that came out of the shaft and levels on the dump. The expenditure for purchase and working so far has been between $7000 and $8000. The production of ore continues.

SILVER BOW COUNTY—SUMMIT VALLEY DISTRICT.

Activity has prevailed at all the principal mines since last report, and all the mills and smelters are running. The shipments of matte and silver-copper ore at the Utah & Northern Railroad office were unusually large, aggregating 380 tons of matte and 650 tons of ore. Nearly all of the latter were shipped to European ports.

NEVADA.

NORTHERN BELLE.—The superintendent writes: As the heat is not so great in the southwest drift of the 5th shaft level, we are able to report better progress, having extended the same 10 feet during the week; total distance, 182 feet; the face having passed into moderately soft quartzite. Work has also been resumed in the south cross-cut, same level, where the formation is quite favorable. The main drift to the west on the 4th shows no change of note, but continues entirely in sulphurets, given low assays. There is a decided improvement in the width of the stope on this level, and the ore is of excellent quality. In the uprise above the 1st, the stopes are producing as usual, the ore being of moderate grade. We are thoroughly prospecting other shaft-levels, but there are no changes of importance to report. Above the adit-level, work is progressing as usual. The 7th and 9th do not present as promising an appearance as last week, but we hope for an improvement. Every thing is running smoothly in and about the mine, and the daily production of ore has been about 43 tons. Both mills are running steadily and doing the usual good work.

COMSTOCK LODE.

A contract with the Risdon Iron-Works, San Francisco, says the *Enterprise*, has been signed for another big hydraulic pump for the combination shaft. The pump is to be completed within one hundred days. It will be of the same capacity as that now in operation, and will be placed at a point from ten to twelve feet below the 2620 level. At this place will be constructed a station 25 feet wide, 14 feet high, and from 90 to 100 feet long. The pump will have upon it over 200 feet more pressure than that at the 2400 level. Once it is in and ready to run, it will release the Cornish pumps now in operation below the 2400, and they will be used below the 2600 level to pump up to the lower hydraulic pump. The cost, which will be a great deal less than the first, will be divided up among the several companies interested in the shaft, will be less than 20 cents per share, and it will be so divided that never so much as seven cents per share will be required at any one time. The putting in of the new pump and the sinking of the shaft to the 3000 level will be of great advantage to all the middle mines.

HALE & NORCROSS.—An official letter says: In consequence of repairs to the air-compressor at the combination shaft, the overhauling of hydraulic pumps and the reopening of the Chollar and Potosi south drift, on the 2600 level, progress in sinking the 2600 winze has been impeded during the whole of this week. This winze is now down 80 feet, and the ore in the bottom looks about the same.

KEYES & WHEELER.—In this claim, north of Monte Cristo, at Seven Mile Cañon, at a depth of 225 feet, a rich black sulphuret ore has been struck. As yet no large body of the ore has been found. In sinking four feet, the deposit has widened from one inch to three feet of ribbon ore and porphyry.

SUTRO TUNNEL.—The report for the week ended August 1st shows that the following temperatures were observed: Tunnel entrance, air 90 degrees, water 120 degrees; shaft No. 1 east, 92; No. 1 west, 96; No. 2 east, 70; No. 2 west, 61; No. 3, 91; No. 4, 90; Combination Shaft connection, 82; Osbiston, 100; C. & C., 88; Julia, 99; Yellow Jacket, 87; Forman, 86. Flow of water in standard gallons per day, 8,032,700.

NEW MEXICO.

MANZANITA CONSOLIDATED.—Assessment-work is doing on the company's claims.

OLD MAN.—Another strike is reported. Glowing reports, with the usual assertion that the ore "runs away up in the thousands," accompany this news.

SOLID FIND PLACER MINING CLAIM.—Gold has been found in a placer four miles north of West Albuquerque. The claim was immediatly located, and will be known by the above name. Work will be commenced at once.

UTAH.

Twenty-five miles east of Black Rock station on the Utah Central, on Cove Creek, there are deposits of sulphur in almost a pure state. Experiments have been made in digging down, and also in boring, to a depth of thirty feet, all the way through sulphur. C. W. Scofield has purchased the property, and already has his machinery at Ogden for refining the sulphur. The machinery is to be shipped to the mines, and will be capable of turning out 150 tons of pure sulphur per day. The process of refining is that of retorts, in which the crude material will be placed, there to be treated by steam under a pressure of eighty pounds per square inch, which will melt the sulphur and separate it from the foreign substances. This pure sulphur will be run into cylindrical blocks weighing 200 pounds each, ready for shipping.

EMMA.—Twenty tons of ore were shipped recently, taken from below the old workings, which sold for $268 per ton. This property is looking very finely, and work is progressing favorably. On the 135-foot level in the new shaft, at the inner end of the Bay City tunnel, a cross-cut, now in 205 feet, has tapped the vein, and from this drifting is going on, and they are also cross-cutting to find the foot-wall. The vein at this point is supposed to be over 100 feet wide. The machinery handles the water very easily, and there is a prospect that the mine will soon begin shipping ore again.

GREAT BASIN CONCENTRATING MILL.—George O. Dickinson and L. Osgood, associated with B. B. Van Deusen, have leased this mill at Stockton, and having entirely reconstructed the old works, are now able to treat the tailings from the former workings of the mill with profit. It is the intention of these men to purchase ores about Stockton, and treat them at the Great Basin concentrator. Samples of concentrates have been brought to this city which show fine results.

ONTARIO.—The tunnel, which was begun in the summer of 1881, and has been in progress ever since, has been finished; it is over 5500 feet long. The Salt Lake *Herald* says that one of the heavy expenses of operating this great mine has been the handling of water, which as greater depth was attained, has been a source of increased labor, anxiety, and expense. It was found difficult not only to handle the water by lifting it from the 600, 700, and 800-foot levels of the mine, but the same labor was attached to lifting the ore from the mine, though, of course, there was no such danger from the ore as there was from fresh outbreaks of water, or from a failure to work of machinery employed to handle the water. The tunnel in question was projected for the purpose of carrying off the water, and thus saving a lift of 600 feet, and also causing a saving in handling the ore. Men are now at work laying in the flumes, and shortly the water, which now finds an outlet at the top of the mine, will be run out from the 600-foot level. The same saving, however, will be made in the handling of ore; indeed, the saving will be greater; for the water is turned loose after it gets to the top, but the ore has to be hauled in wagons from the mine to the mill. By means of the tunnel, however, ore can be sent from the 600-foot level down to the mill on cars, thus saving the expense of hoisting 600 feet and then of loading and hauling to the mill and unloading again. The tunnel cost the Ontario over $20 per foot, and there are over 5500 feet, or something over $110,000.

WYOMING.

The Silver Crown District is making rapid strides toward a permanent and paying mining camp. The mines are owned principally by Omaha, Chicago, and Cheyenne parties. This district is situated near Granite Cañon, and southeast from Laramie. At the principal mine, fully $50,000 worth of copper ore is on the dump. A town-site has been located near the mines, and twenty-six men are now at work. The country is staked out for miles and miles thereabouts, and new arrivals are reported daily. A portion of the country lying between the new mines and Laramie is also undergoing thorough prospecting.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Aug. 17.

The mining market this week has been very dull, and there is but little of interest to note. Prices generally have ruled weak, with the exception of one or two low-priced stocks. The Comstocks were quite weak, although but moderately dealt in. To-day, Navajo sold very weak, with a small business. Below will be found a complete summary of the market. The total number of sales aggregates 137,900 shares, as against 193,655 last week.

The Comstock shares have been quiet and weak. California, under a small business, was quite weak, declining from 42 30c. Consolidated Virginia was moderately dealt in at irregular prices; it sold from 62@55@58c. Sierra Nevada has been quiet and weak, selling from $5.13@$4.40. Union Consolidated was dealt in to the extent of 400 shares, at $5.38@$5. Ophir sold at $3.50. Hale & Norcross was quiet and steady, selling from $6@$5.75. Savage sold from $2.20@$2.10, assessment unpaid. Yellow Jacket, with one small transaction, sold at $3.05. Sutro Tunnel was quiet and steady, selling from 19@20c.

The Leadville stocks were very quiet and very steady. Amie was quiet and weak, selling from 17@14c. Chrysolite was moderately dealt in at steady prices; it sold from $1@$1.10. Dunkin records small transactions at steady prices, selling from 23@20c. Leadville sold at 35c. Little Chief has been moderately dealt in and was steady, selling from 42@41c. Little Pittsburg was quiet and steady at 66c. Climax records a small business at steady prices, selling from 10@9c.

The Bodie stocks were very quiet. Bodie Consolidated was weak at 39@35c. Standard was steady, under small transactions, selling from $5.50@$6. Bulwer records one transaction at 70c.

The Tuscarora stocks record but a small business, and were steady. Grand Prize sold from 27@30c., with a business of 400 shares. Argenta was quiet and steady, selling from 15@20c. Belle Isle sold at 35c. Navajo had a small business and was quite weak; it sold from $3@$2.25. Elko Consolidated has been active and steady, selling from 17@15c.

In the miscellaneous list, Alice has declined during the week, but rallied to-day, and was stronger; it sold from $2.40@$2.20@$2.40. Eureka Consolidated was quiet and steady, selling at $6.50, assessment paid, and from $5.75@$6, assessment unpaid. Horn-Silver has been quiet and a little weak; it sold from $6.50@$6.25. Northern Belle has suffered a slight decline, under a small business, selling from $6.50@$6.25. Robinson records an active business at weak prices; it sold from 75@62c. Sierra Grande has been moderately dealt in, and has been steady; it sold from $1@1.15.

Alta-Montana has been quiet and steady, selling from 5@6c. Barcelona continues to be very actively dealt in, but has suffered a slight decline; it sold from 45@37@39c. Bradshaw was quiet and irregular at 26@24@25c. Caledonia has been quite weak under a small business, declining from 81@70c. Decatur records small transactions at 3c. Eastern Oregon has been actively dealt in, and has been strong; it sold from 87@93c. Harlem declined from $1.40@$1.25, with a business of 1300 shares. Oriental & Miller was quiet and steady at 14c. Rappahannock sold from 5@7c. Sonora Consolidated has been actively dealt in, and has been a little weak; it declined from 29@25c. South Hite records a small business at weak prices, selling from 5@3c.

The property of the Alta-Montana Company has passed into the hands of the Helena Mining and Production Company, with a capital of $3,000,000 divided into 600,000 $5 shares. The new company gives one share for every ten shares of the old company, provided the exchange is made on or before the 15th of September. The new company has a bonded indebtedness of $600,000, given in part payment for the property, having ten years to run, 6 per cent interest, payable semi-annually, beginning in eighteen months. Parties interested in the new company have, we understand, induced the Northern Pacific Railroad to build an extension to Wickes.

At the meeting of the stockholders of the Green Mountain Company this week, we understand it was reported that the mine was paying for all but the dead-work, leaving a deficiency of from two to three thousand dollars per month. An effort has been made to raise $30,000 toward meeting the past expenditures for this purpose, and the sum which it will probably require monthly to the end of this year, when it is expected the Blake chute will be struck. It is reported that $20,000 have been raised.

The tunnel of the Ontario Silver Mining Company has been completed, so that the strain on the pumps will be relieved.

DIVIDENDS.

The Homestake Mining Company, of Dakota, announces its July dividend of $50,000, payable at the office of Lounsbury & Haggin, Mills Building, No. 15 Broad street, on the 25th. Transfers close on the 20th. Total of dividends to date $2,162,500.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows for the week:

On last Friday, the market was sluggish and uninteresting at about $1.08⅛@$1.09, but late in the day a spirited buying rapidly advanced the price to $1.11 on the report that Porcupine No. 9 well was in and showing very poorly. Before the close, however, the price reacted to $1.09, when it was learned that the well promised to be good. The next day, Saturday, the well was proved to be a large one, and it was evident that this extended the area of productive territory in Balltown; but, strange to say, the market did not respond to this bearish news. On Tuesday, prices actually advanced to $1.10¼, at which they closed, and Wednesday they sold still higher at $1.11⅛. Meanwhile, two other large wells had come in, Balltown No. 6 and McCalmont No. 5. During all this time, the stock market was exceedingly weak and almost on the verge of a panic; and had the petroleum market been left to its fate, it must have declined.

Further to show the tactics of the Standard Oil Company, it deliberately advanced the price of refined from 7⅝ cents per gallon to 8⅛ cents between Wednesday and to-day, though there is a very light export demand, and the domestic trade not yet due. This doubtless is intended to help bull oil, and the clique now in control of the market is probably both able and disposed to advance prices. Porcupine No. 9 was drilled deeper on Wednesday evening, increasing its flow to about 2000 barrels the first twenty-four hours. This is on the extreme northern line of Balltown, and opens up to great possibilities the territory between Balltown and Cherry Grove. If oil goes up to near $1.15 during the next few days, it ought to be a good sale for those who will remain short. Russia is coming every day into more active competition with American petroleum on the continent. California and Missouri give promise of opening some new producing wells, and the present stock of crude is the largest in the history of the trade.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Aug. 11.....	$1.08¾	$1.10½	$1.08¼	$1.08½	1,923,000
13.....	1.08⅛	1.08¾	1.07¾	1.08⅛	1,853,000
14.....	1.08	1.10⅝	1.08	1.10⅝	3,044,000
15.....	1.09⅝	1.11⅝	1.09⅛	1.09¾	3,545,000
16.	1.08¾	1.09⅞	1.08¾	1.09⅝	3,163,000
17.....	1.10⅝	1.11⅝	1.09⅞	1.10⅛	5,575,000
Total sales.					19,103,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, Aug. 16.

There has been but little doing the past week in mining stocks, the interest in the general market having absorbed all the attention of operators. The copper stocks are held mostly by investors, very few being bought on margins, and consequently, in a period of depression such as we have had the past week, there is no selling out "under the rule" or forcing stocks for sale because margins are exhausted. Calumet & Hecla declined on small sales to $241, but quickly rallied again to $245, the closing price of last week. It is worthy of notice that so little of this stock out of the 100,000 shares of the company is put upon the market, showing the confidence of the holders in its permanent character as an investment security. Quincy, which is more of a speculative character, is much more largely dealt in, but has fairly maintained its price against an adverse market, having declined only $1 per share, with sales of 200 or 300 shares, mostly in small lots, at $46@$45, closing $45 bid. Osceola also declined $1 per share; sales at $18½. Pewabic sold at $3¼@$3. Allouez, at $1½. Altantic, 25 shares, at $10; last sale $12, July 20th.

In silver stocks, dullness reigns. The transactions for the week, all told, are not equal to one good day's work in ordinary times of activity. The commission brokers complain of the absence of orders, and what little is done is principally room trading. Bonanza declined from $1⅛@$1¼, but later advanced to $1⅝, sales. Catalpa declined from 42½@37½c., but closed a little firmer, with sales at 42½c., and 40c. bid. Harshaw sold at 50c. Silver Islet, at $3⅛. Bowman Silver seems to have got into a rut at 16c. bid, 17c. asked, with now and then a sale at both figures. Massachusetts & New Mexico, dull at 4c. bid for small lots, and 3c. for 5000-share lots, and but little offering under 5c. The bonds are steady at 11@13 per cent.

3 P.M.—At the afternoon Board, Catalpa sold at 40c. Quincy, offered at $45. Huron, $1⅝ bid. Silver Islet, $3 bid. Bonanza, $1½ bid. Crescent, 12½@15c. The rest of the market unchanged.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended August 17th, as compiled from various sources, amounted to $210,000, as against $250,000, reported for the previous week. The receipts from January 1st, 1883, to date are $7,177,974.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended August 11th	$249,460
Corresponding week last year	290,000
Since January 1st, 1883	8,136,524
Corresponding period last year	42,450,213

Imports.

Week ended August 11th	$153,746
Corresponding week last year	32,929
Since January 1st, 1883	7,851,665
Corresponding period last year	2,261,801

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £396,000 bullion—principally from domestic sources—and the proportion of its reserve to its liabilities was raised from 45⅝ to 46 9-16 per cent, against 37⅞ per cent at this date a year ago. The weekly statement of the Bank of France shows losses of 1,725,000 francs gold and 1,325,000 francs silver.

METALS.

NEW YORK, Friday Evening, Aug. 17.

Copper.—So far as Lake copper is concerned, the situation is practically unchanged. It is occasionally procured at 15c., and we note an export sale of 100,000 pounds at that figure. We quote nominally, 15@15¼c. In other grades, the range continues at 14@14½c., according to quality, 600,000 pounds of Baltimore in lots having been sold, some of it at 14¼@14⅝c. The export of refined ingot copper for the first six months of the year was 11,483,172 pounds of Lake and 1,219,200 pounds of Baltimore, Orford and other brands. The engagements are understood to cover considerable additional quantities. Messrs. Thomas J. Pope & Co., of this city, have printed the following estimate of the output for 1883:

	Pounds.
Arizon and New Mexico	20,000,000
Montana	21,000,000
All other places, except Lake	7,000,000
	48,000,000
Lake Superior	56,000,000
Total	104,000,000
Exports already shipped and contracted to be shipped	35,000,000
Namely: Copper, outside of Lake	Pounds. 15,000,000
Lake copper	20,000,000
Leaving for home consumption for the year 1883	69,000,000

We have reason to believe that the product of the mines outside of Lake will be much closer to 54,000,000 pounds, and that the Lake producers will not fall short of 58,000,000 pounds, which would make the total 112,000,000 pounds.

The engagements of Lake copper for export and of metal for cartridges are probably not more than 14,000,000 pounds. On the other hand, the engagements of copper in various forms from other sources are heavier, probably not less than 20,000,000 pounds, so that there would be left for home consumption 78,000,000, which leaves us with a fair margin for further exports of Montana mattes and ores, assuming our consumption to be at the rate of 72,000,000 per annum.

With such figures as those given by us, which are conservative, there is every reason for a hopeful view for the future.

In England, Chili Bars were quoted to-day £64 f. o. b., which is the usual level of the past month. Best Selected, however, has improved to £69 f. o. b., which is encouraging, because it was here that the principal weakness has been shown of late.

The statistical reports published in England are bewildering in number, and are treated in a widely varying manner. We choose the two following, knowing them to be as reliable as they can be procured. The statistics of Messrs. James & Shakspeare below estimate the supply and demand:

STATISTICS OF COPPER—ENGLAND AND FRANCE.

	Jan. 1 to June 30. 1883. Tons.	1882. Tons.
Imports copper into England per Customs	48,573	42,878
Of which passed through public warehouses	33,916	29,669
Giving direct supply to smelters	14,657	13,209
Deliveries from public stocks, England	32,633	31,835
To which add direct supplies, as above	14,657	13,20.)
Making total delivery of	47,290	45,044
Of this were exported (reduced to pure copper)	29,588	26,139
Leaving for home use	17,702	18,905
English imports, as per Customs returns	48,573	42,878
French imports of foreign (direct)	8,048	7,299
Total supply, England and France	56,621	50,177
English consumption, as above	17,702	18,905
English exports (in fine copper)	29,588	26,139
Deliveries from French warehouses	8,304	6,550
Total consumption, England and France	55,594	51,594

Those of Messrs. Henry R. Merton & Co., of London, give details of the stocks, and the quantities afloat and chartered.

	July 31. 1883. Tons.	1882. Tons.	
Stocks in England and France:			
Chili bars	23,997	20,711	Liverpool and Swansea.
" ingots	436	1,105	
" ores and regulus (fine)	1,812	1,977	
" other stuff (fine)	4,014	2,375	
Foreign copper (chiefly Australian) and landing	4,531	7,545	London.
Chilian and other bars	2,094	3,244	Havre and Bordeaux.
Other copper	575	370	
	37,459	37,327	
Afloat and chartered from Chili to England and France:			
Ores and regulus (fine)	359	2,228	Advised by mail.
Bars and ingots	6,964	2,209	
Ores and regulus (fine)	700	1,600	Advised by cable.
Bars and ingots	2,800	3,600	
	48,282	46,964	
Afloat from Australia to London:			
Fine copper	257	650	Advised by mail.
Fine copper	783	1,250	Advised by cable.
Totals	49,322	48,864	

Tin.—There is a firmer feeling. The large arrivals of the past week have been absorbed and for the time being the stocks are again firmly under control. In large lines, Straits and Australian are quoted 21@21⅛c., while Malacca, the spot stock of which is reduced to 50 tons, is held at 21¼c. Straits for August shipment is offered at 20⅝c. London cables to-day £93.

Lead.—The market has been dull and has exhibited further signs of weakness. There have been jobbing sales only at 4·25c. with rumors of 4·20c. for Common, and 4·25 for Refined. Offers at 4·20c. can hardly be obtained. It is stated that some of the refiners, who find it hard to get the raw material, are indifferent, in fact, would not object to seeing prices fall off further still. London is as low as it ever has been, and soft Spanish can be laid down at 4·80c., duty paid. A small quantity, about 2000 tons, is annually brought in to be exported under the drawback clause.

From St. Louis, Messrs. John Wahl & Co. wire us as follows:

Our market is unchanged, being quiet, with prices the same. Sales will not aggregate 250 tons of Refined at 4c., and 30 tons of Common at 3·95c.

From Chicago, Messrs. Everett & Post send us the following dispatch:

The market remains in the same condition, showing, if any, a shade of weakness. Offerings, however, are moderate only. There is a general disposition to buy at 4c., but there is none offering at that. Prices are nominally 4·03@4·07½c.

Spelter.—It is reported that some of the Western producers are showing a disposition to hold back at present prices, and only the brands of works recently started, being comparatively unknown, are available at 4⅜c., the others being held at 4½@4¾c.

Antimony.—There is little doing, quotations remaining 10¼c. for Cookson's and 9¼@9⅜c. for Hallett's, for jobbing lots.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Aug. 17.

Mr. Edward J. Shriver, Secretary of the New York Metal Exchange, publishes the following returns for 136 furnaces:

1883.	No. 1.	No. 2.	Forge and lower grades.	Grade not specified.	Total.
Stocks July 1st	14,538	24,192	50,058	21,226	110,014
" August 1st	14,817	20,127	30,365	21,250	106,459
Prod'ct'n in July	19,327	7,708	25,704	14,354	67,093

"Forge and lower grades" includes some charcoal and Bessemer pig.

American Pig.—If any thing, the condition of the market has grown a shade more unsatisfactory. While No. 1 is certainly not in over-supply and is firmly held, other grades are available in full quantity, and in some cases can only be moved by making round concessions. We continue to quote $22@$23.50 for standard to choice No. 1, the Crane Company claiming to $23, ordinary brands being obtainable at a concession of 50c.; $19.50@20.50 for ordinary to choice No. 2; and $18@$20 for inferior to choice Gray Forge. Bessemer Pig has sold to the extent of 5000 tons at $21 at tide. Spiegeleisen has been dull, the higher grades at $30.50, and the lower at $25.50@$26.

The week has been an exceedingly quiet one at the Exchange, no transactions being recorded.

Scotch Pig.—Business during the week has been dull at about our quotations. Arrivals are moderate this week, aggregating 1400 tons, and freights are cabled better, 8s. from Glasgow.

We quote ex ship: Coltness, $23.75@24; Langloan, $23.75@24; Summerlee, $23; Dallmellington, $21@$21.50; and Eglinton, $20.50@$21.

At the Exchange, the following slightly lower cable quotations were received: Coltness, 60s. 3d.; Langloan, 61s. 3d.; Summerlee, 57s.; Gartsherrie, 56s. 9d.; Glengarnock, at Ardrossan, 55s.; and Eglinton, at Ardrossan, 49s.

Rails.—For early delivery there is little doing, the mills being fairly full; beyond that, the quotations of of agents, $37.50@38, are not tempting buyers, who look forward to lower figures.

Old Rails.—The firm tone still prevails, though transactions are limited. We quote $22.50@$23.

Scrap.—Small sales are made. We quote, ex ship, $22.50@23.

Philadelphia. August 17.

Pig-Iron.—The improvement which a great many brokers and makers predicted in July to take place in August has not shown itself as yet, although the expectation is still strong of an active demand before the opening of September. It is based upon the fact that stocks of desirable irons of special and standard brands are in light supply. Apparently, there is a need for much more activity on the part of consumers than has been exhibited. But the tendency is to lower prices, and hence the delay indulged in by every one who can postpone the placing of large orders. Part of this inactivity is due to the knowledge that some companies have large stocks.

No. 1 Foundry is quoted at $22@$23, tide-water; Common, $21@$21½. Best No. 2, $20.50. Poorer grades are $19. Mill irons command $20 for most of the iron selling. The poorer grades are neglected. The furnace quotation is $17.50, and this is pretty generally adhered to on all sides. Makers show considerable determination, and are justified in so doing by the fact that that quotation represents the minimum price at which iron can be sold to cover cost. There are inquiries in the market for large lots, but the weakening tendency has induced buyers to withdraw some of their offers. For a number of well-known brands, $18 is adhered to. Scotch iron is selling in a quiet retail way. One lot of 5000 tons of Bessemer iron has been sold for shipment at $21 and other offers are in hand at $20.50. Spiegeleisen is selling at $31.25, with offers at 50@75c. less for large lots.

Blooms.—Charcoal Blooms sell in small lots at $57.50. Anthracite Blooms are quiet. Muck Bars are quoted as usual, $34@$35, with some business at the inside figure.

Merchant Iron.—The demand for merchant iron is irregular, and prices fluctuating, because of the continuance of the competition heretofore reported. Card rates are 2·30c. Selling prices, 2@2·20c. Several orders have been sent to country mills at 2c., and there are negotiations in hand to-day for several hundred tons at that price, although the iron is not strictly first-class. The off-setting advantage of the low prices is a large prospective demand, which imparts a steady tone to the market, although complaints are frequent as to the cutting of prices without cause. A good deal of iron is going in small lots at 2·15@2.20c. from mill and store.

Nails.—The nail trade has been active for the past week, and some few inquiries have just been received from jobbers who are willing to lay in a few hundred-keg lots, for retail requirements, at a little less than asking prices. Makers are not very anxious to book business of this kind; but dealers have declined this week to buy, unless concessions were allowed.

Plate and Tank Iron.—A fair amount of business, both in large and small lots, has been transacted, and mills are all in good shape, as prices are 2·40@2·50c. for Tank, and 3@3¼c. for Shell.

In *Structural Iron*, some additional business has been placed, and inquiries are coming along to fill large specifications at last week's prices. Sheet-iron continues to improve in demand, and some concessions have been allowed on a few large lots placed this week. Small lots are firm at card rates.

A fair amount of inquiry is coming along for wrought pipes and tubes, which are moving in small lots at from 70 to 75 per cent off for gas and steam pipe and 60 for tubes. Makers report a fair inquiry, and see a large demand in the near future.

Steel Rails.—Steel rails are strong and steady at $38@$38.50, with the average business. A number of offers have been made at prices away below these figures, but without any result, as mills have as much business as they care for, excepting on their own terms.

Old Rails are not to be had excepting on shipments, and agents are asking $23.50 in some cases; $23 offered, but no business is heard of.

Scrap-Iron is unchanged, and several buyers are in the market for hundred-ton lots and over, but selling prices are too high. Railroad Scrap is held at $25, and cargo lots $22.50. Crop-Ends, $23.

Pittsburg. August 16.

To-day's quotations are $17@$18 for Neutral Mill; $18@$18 50 for Red Short; $19.50@$20 for Native Ore Foundry; $22 for Lake Ore Foundry. The only peculiarity of the market this week is the fact of an increasing number of inquiries for Bessemer, Forge and Foundry. The improvement has induced the holders of desirable makes of iron to hold to higher selling prices. The resumption of mills in September will lead to a larger demand, and manufacturers have endeavored this week to cover September requirements, but failed to do so, and will risk buying random lots when needed. Bessemer is held at $21. Several offers are in hand at $20. Muck Bar is quiet at $34.50. A good many consumers of merchant iron have placed orders for 50-ton lots at 1·90c. Small lots are 2c. Offers are in hand at 1·75@1·80c. for larger lots, and there is a disposition to meet that demand. Nails are strong and steady at $2.90. Sheet and galvanized iron is in good request, and mills are filling up. Steam pipes are 75 per cent off. Steel is moving quietly in small lots; Crop-Ends are quoted at $25@$26; Steel Rails, $38. Business is restricted to small lots. Large lots will not be placed for a few weeks to come, unless makers should decide to take less than they now ask. Rail fastenings are $2.60 for Spikes.

COAL TRADE REVIEW.

NEW YORK, Friday, Aug. 17.

Anthracite.

The anthracite coal trade here is still very dull, and there is no improvement whatever to report. June purchases have been filled and appear to have pretty thoroughly loaded up retailers, many of whom could not take any more coal even if they would. The result is, that there is considerable pressure to sell coal, especially as the production is large, and the manufacturing interests are very dull. The Pennsylvania Coal Company has advanced its circular prices 10c. on egg, 20c. on stove, and 15c. on chestnut, and as the managers of it are known to be conservative, considerable stress is laid on the fact as an indication of an improvement in the trade. The company, we presume, is warranted in taking this step, which brings its nominal prices nearer those of the others; but we have certainly not been able to trace any symptoms of a better general feeling, and attribute their action to special reasons. The trade is looking forward to September with some interest, and the opinion is general that an advance will be announced. There are rumors, however, that the councils of the magnates of the trade are not entirely unanimous on this subject.

John H. Jones, official accountant, has published the following statement of the anthracite tonnage for the month of July:

	July, 1883.	For year 1883.	For year 1882.	Difference.
Phila. & Reading RR.	1,026,481	4,671,736	3,560,173	I. 1,111,563
Central RR. of N. J.	*.....	1,745,399	2,304,445	D. 559,046
Lehigh Valley RR.	†497,741	3,346,470	3,168,435	I. 178,035
Del., Lack. & W. RR.	427,646	2,644,714	2,460,393	I. 184,321
Del. & Hud. Canal Co.	‡279,262	1,810.423	1,662,303	I. 148,120
Penna. RR.	240,609	1,449,578	1,275,289	I. 174,289
Pa. Coal Co.	121,597	774,780	756,383	I. 18,397
N. Y., L. E. & W. RR.	22,349	183,353	137,680	I. 45,673
Total.	2,615,686	16,626,454	15,325,100	I. 1,301,353

* Included in tonnage of Philadelphia & Reading Railroad.

† This amount includes the production of the mines of the State Line & Sullivan Railroad Company, amounting to 6029 tons.

‡ In addition, there were 42,748 tons transported from the mines by the Delaware & Hudson Canal Company, during June, which is included in tonnage of other interests.

The stock of coal on hand at tide-water shipping points, July 31st, 1883, was 502,159 tons; on June 30th, 1883, 592,309 tons; decrease, 90,150 tons.

Bituminous.

Bituminous coal does not appear to have reached bottom yet, and we hear of sales of Clearfield at $3.45. The competition is exceedingly sharp. Cumberland is nominally $4@$4.40 alongside, according to quality.

STATISTICS OF COAL PRODUCTION.

The Transportation of Coke over the Pennsylvania Railroad for the week ended August 11th, and year from January 1st:

Tons of 2000 lbs.	Week.	Year.
Penn. RR. (Alleghany Region)	954	53,707
West Penn. RR.	2,414	64.527
Southwest Penn. RR	40,551	1,262,799
Penn. & Westmoreland Region, Pa. RR	4,023	136,649
Pittsburg, Penn. RR.	...	501
Snow Shoe (Clearfield Region)	165	12,014
Total	48,107	1,530,194

Belvidere-Delaware Railroad Report for the week ended August 11th:

	Week.	Year. 1883.	Year. 1882.
Coal for shipment at Coal Port (Trenton)	3,278	64,847	52,678
Coal for shipment at South Amboy	13,640	475,087	512,025
Coal for distribution	16,204	473,796	427.733
Coal for company's use	5,132	95,636	77,891
Total	38,254	1,109,364	1,070,327
Increase		39,037	
Decrease			

Horsford's Acid Phosphate,

Very Satisfactory in Prostration.

Dr. P. P. GILMARTIN, Detroit, Mich., says: "I have found it very satisfactory in its effects, notably in the prostration attendant upon alcoholism."

WANTED.—A SITUATION; FIFTEEN years' experience in smelting, refining, and assaying lead, copper, and silver and gold. Speaks English, Welsh, French, and Spanish. Highest testimonials as to character and ability. Address, C. M.

DIVIDENDS.

HOMESTAKE MINING COMPANY, MILLS BUILDING,

NEW YORK, Aug. 13, 1883.

DIVIDEND NO. 60.

The regular monthly dividend of FORTY CENTS per share has been declared for July, payable at the office of the Transfer-Agents, Lounsbery & Haggin, Mills Building, 15 Broad street, on the 25th inst.

Transfer-books close on the 20th inst.

LOUNSBERY & HAGGIN, Transfer-Agents.

SAN FRANCISCO, Aug. 4, 1883.

THE BODIE CONSOLIDATED MINING CO. this day levied assessment No. 3 of 50 cents per share, delinquent September 10th. Sale day, October 16th. Same may be paid at the office of Laidlaw & Co., 14 Wall Street. GEO. W. SESSIONS, Secretary.

OFFICE OF THE JOCUISTITA MINING COMPANY, MILLS BUILDING, 15 BROAD STREET, NEW YORK, Aug. 8, 1883.

DIVIDEND NO. 9.

The Jocuistita Company has this day declared a quarterly dividend of FIFTY THOUSAND DOLLARS, being fifty cents (50c.) per share, payable at the office of Lounsbery & Haggin, Mills Building, No. 15 Broad street, on the 31st inst.

Transfer-books close on the 25th inst.

R. P. LOUNSBERY, President.

STEAM PUMPS.

FOR SALE.—A large number of Steam-Pumps of all makes, and ranging in size from small tank or boiler feeds up to very heavy service machines.

While the stock lasts, good bargains are open for Miners, Water-Works, Rolling-Mills, Furnaces, or any one needing to move fluids by steam. Call upon or address

JOHN A. HINCKLEY, Purchasing Agent of THE UNITED PIPE LINES, OIL CITY, PA.

SMELTING-WORKS FOR SALE

The smelting-works, with a capacity of from 60 to 80 tons per day, situated at Socorro, New Mexico, upon a switch of the A. T. & S. F. Railroad.

These works are entirely new, and are equipped with all the most modern improvements. For sale for lack of capital to run them. For further information address

WILLIAM H. RENAUD,
Care John J. Adams & Co., New Orleans, La.
Or WM. VANSLOOTEN, 633 Broadway, New York.

Important to Iron and Steel Workers.

Complete Plants

furnished for utilizing low grade ores by concentration and

Wilson Direct Process.

Low-grade or finely-pulverized ores made *directly* into first-class blooms, showing by long and practical tests a

SAVING OF OVER 25 PER CENT

over any other process in use.

Durability, Efficiency, and Economy Guaranteed.

Address, BUCHANAN & JENNINGS, 108 Liberty Street.

PHILADELPHIA SHAFTING WORKS.
GEORGE V. CRESSON,
18TH AND HAMILTON STREETS,
PHILADELPHIA, PA.

MESSRS. WELLS, FARGO & CO., on the first of August, opened for business with Mexico to all points on the Mexican Central, Mexican National, and Isola & Pachuca railroads.

M. ALEXANDRE POURCEL, the eminent metallurgist, who has contributed so much toward making Terre Noire one of the most famous steel-works of Europe, has resigned and has accepted the charge of the large steel-works which are now building at Bilbao, Spain.

WE regret to announce the death, at Real del Monte, Mexico, of WILLIAM SULLIVAN SCHLEY, M.E., a graduate of the Clausthal School of Mines. By industry and perseverance, after many years of faithful work under adverse circumstances, he had reached the point where he was just beginning to see a brighter future open out before him.

GASES IN IRON AND STEEL.

The most lively and sustained controversy during the past few years in metallurgical circles has been that relating to the gases occluded and inclosed in iron and steel. Aside from the fact that iron-masters and steel-makers have learned to take a much deeper interest in researches formerly scorned as merely "theoretical," the direct bearing of the question at issue upon important practical points has contributed to make the controversy one which has been closely watched. We have repeatedly referred to the subject in giving an outline of the work of MÜLLER, PARRY, and others, and the more polemical writings of M. ALEXANDRE POURCEL, Dr. WEDDING, and a group of metallurgists who took a part in the discussion. Of late, few facts based upon experimental work have been brought forward, and the more recent contributions have not been remarkably profitable. Particular interest attaches, therefore, to the latest data gathered by that indefatigable worker in this field, Dr. FRIEDRICH C. G. MÜLLER, of Brandenburg, Germany. Following his example in the first installment of his paper, printed in *Stahl und Eisen*, we shall, for the present, confine ourselves to the presentation of a summary of his array of new data, leaving their discussion to a future period.

Iron and steel, like many other metals, possess the property of being able to absorb gases, their capacity to absorb hydrogen being greatest, while it is less for carbonic oxide, carbonic acid, and nitrogen. In chilling, a part of the gas escapes, giving rise to phenomena which destroy the continuity of the solid metal, and unfavorably affect its mechanical properties. Metallurgists are less interested in the cause than in the effect, and the porosity of steel, being a serious flaw at times, attracted study at an early date. The first efforts directed toward the remedying of the evil in this country, where Mr. W. R. JONES took the lead, were to prevent the escape of the gases by applying pressure during the process of solidification, a purely mechanical method, therefore. At Terre Noire, it was discovered that the addition of an alloy of silicon, manganese, and iron had a quieting effect upon steel, and the theory was advanced that this was due to the decomposition of carbonic oxide by silicon, it being accepted as a fact that blow-holes were caused by the entanglement of bubbles of that gas during the chilling of the steel. This theory was rudely shaken by the discovery that the gas in steel was chiefly hydrogen.

Mechanically, the form of the blow-holes was carefully investigated. A common form is that of porous tops, which is most easily dealt with. A more dangerous form is a core consisting of a series of cavities extending along the central portion of the ingot. A third kind of blow-holes is a large number of elongated fine horizontal cavities extending from the sides of the ingot toward its center.

There are two distinct phenomena producing unsound ingots. The first, which may be termed the "scintillating" of the steel, is due to an escape of gas from the metal at the moment of its solidification. This phenomenon does not necessarily cause unsoundness except in the top of the ingots, unless the escape of the gas in the central portion, chilling last, is cut off by the solidification of the upper part of the ingot. In that case, the ingot will show a core of blow-holes. The main point in casting such steel would therefore be to keep the top open for the escape of gas. The second, that of "rising" steel, is not accompanied by the expulsion of many particles of molten metal, but is characterized by the more or less rapid rising of the metal in the mold. The steel may appear to be completely quiet and dead in casting, and yet in solidifying will show the phenomenon noted, which causes the formation of the horizontal elongated blow-holes radiating from the sides to the center, honey-combing the entire ingot in extreme cases; while in less pronounced instances the blow-holes are nearer the center, there being a thick solid shell around them. While steel may scintillate and at the same time show a tendency to rise, as basic steel sometimes does, the phenomena are apparently due to two entirely distinct causes. The rising is, according to MÜLLER, due entirely to the presence of occluded hydrogen, while the "scintillating" seems to be caused rather by the escape of carbonic oxide.

Dr. MÜLLER has added only a few analyses to those already published of the character of the gas in the blow-holes in ingot steel. But as these are of interest, referring to basic steel, we give them below:

ANALYSES OF GAS IN BASIC STEEL.

	Quantity of gas. Per cent.	Carbonic oxide.	Hydrogen.	Nitrogen.
I. Soft, made with 2½ per cent 35 per cent ferro. Scintillating. Rising a little.	36	0·6	85·4	14·3
II. No final additions. Quiet. Scintillating little. Rising slowly.	20	0·0	64·5	35·4
III. Made with 5 per cent 14 per cent silicide and 2½ per cent 70 per cent ferro. Rising quietly. Ingot pretty sound.	22	0·4	86·4	12·7
IV. Made with 5 per cent 14 per cent silicide. Rising quietly. Ingot solid.	6	0·0	54·7	45·3

It is worthy of mention that, in spite of the large additions of silicon and manganese in Nos. III. and IV., the steel had only traces of silicon and 0·4 per cent of manganese, while at least 0·3 per cent of phosphorus

Digitized by Google

was reduced. In another case, the percentage of phosphorus in the steel rose, after an addition of 5 per cent of silicide, from 0·106 to 0·515 per cent, while the silicon ran only 0·011 per cent.

Dr. MÜLLER'S principal labors were, however, directed to the analysis of the gas escaping from the steel during the process of solidifying; the only attempt previously made in this direction being that of Mr. J. STEAD, of Middlesborough. Dr. MÜLLER at first collected the gas by using bottom casting and conducting the displaced and accumulating gas through a pipe in the closed top. This method yielded results that were not strictly correct, even after deducting the oxygen found and a four-fold quantity of nitrogen, as representing the air in the mold, because a part of the gas was probably consumed by combustion, so that the nitrogen is too high. In order to overcome this defect and get rid more thoroughly of the air, a second method was used. The ingots were cast from the top in the usual way, and then the remaining space in the mold was quickly filled with pure white quartz sand, thus displacing the air and preventing ignition of the escaping gases before they were collected. A clay cover was luted on top of the ingot and the gas collected through a pipe. The letter *b* affixed to the analysis will, in the following, denote that the gas was collected by the earlier; and the letter *t*, by the later and better method.

The gases escaping from chilling pig-iron were found to have the following composition:

ANALYSES OF GASES ESCAPING FROM PIG-IRON.

	Carbonic oxide.	Hydrogen.	Nitrogen.	Carbonic acid.
Gray Bessemer pig	37·3	58·3	0·5	3·9
Spiegeleisen	48·7	49·5	0 5	1·3
Basic Bessemer pig	39·6	46·8	10·0	3·6

The analyses of these grades of pig were as follows:

Pig:	Carbon.	Silicon.	Manganese.	Phosphorus.
Gray Bessemer	3·688	1·680	1·930	.....
Spiegeleisen	4·180	0·253	7·370	.....
Basic Bessemer	3·099	0·203	0·736	3·025

The fact that the gas gathered in pig-iron by drilling is high in hydrogen and nitrogen, but low in carbonic oxide, while the latter gas, as is shown, is found in a large percentage in the escaping gas, proves that pig-iron when chilling is incapable of retaining the carbonic oxide previously absorbed.

Bessemer steel made at Bochum, which in casting shows few signs of scintillating and rising, yielded gas of the following composition, the rail steel ranging between 0·23 and 0·28 in carbon, 0·15 and 0·25 in silicon, 0·5 and 0·6 in manganese, and 0·06 and 0·08 in phosphorus, while the spring steel carried from 0·48 to 0·53 of carbon, 0·15 to 0·25 silicon, 0·8 to 0·9 manganese, and 0·06 to 0·08 phosphorus.

ANALYSES OF GAS ESCAPING FROM INGOT STEEL.

	Carbonic oxide.	Hydrogen.	Nitrogen.	Carbonic acid.
1. Rail steel (*t*)	37·3	47.3	7·9	7·5
2. Spring steel (*t*)	34·0	49·5	8·6	7·9
3. Spring steel (*b*)	45·9	41·4	9·9	2·8
4. Rail steel, first ingot	38·7	51·3	7·2	2·8
5. Rail steel, last ingot	43·4	46·9	6·6	3·1
6. Solid spring steel, first ingot	48·2	44·5	2·5	4·8
7. Solid spring steel, last ingot	42·5	36·5	17·1	3·7

Analyses 4 and 5 and 6 and 7 were made to ascertain whether there was any change in the composition of the gas issuing from the steel, after remaining in the ladle for a time; and therefore the first and last ingots of a heat were examined, the result being a slight relative decline in the hydrogen and an increase in the carbonic oxide. In all cases, the metal examined made solid castings. In order to ascertain whether the gas was different in composition in porous steel, the following analyses were made: No. 1 rose slightly, it being possible to keep in the ingot by pouring water on it. No. 2 had to be divided. No. 3 rose very much. Dr. MÜLLER examined also Bessemer steel completely decarbonized before the final addition of spiegeleisen, which rose considerably and developed much gas, the two samples 4 and 5 being taken one after the other from the same ingot.

A parallel experiment was made with open-hearth steel, the sample being cast before recarbonization.

ANALYSES OF GAS ESCAPING FROM INGOT STEEL.

	Carbonic oxide.	Hydrogen.	Nitrogen.	Carbonic acid.
1. B. Rail steel, rising slightly (*t*)	38·4	51·0	2·2	8·4
2. B. Rail steel, rising strongly (*t*)	31·5	39·2	21·6	7·7
3. B. Rail steel, " " (*t*)	70·7	20·7	6·5	2·1
4. B. Steel, not recarbonized, rising, first sample (*t*)	18·6	54·2	24·9	2·3
5. B. Steel, not recarbonized, rising, second sample	18·1	52·9	26·8	2·2
6. O. H. Steel, not recarbonized, rising, first sample	48·0	35·1	15·4	1·5
7. O. H. Steel, not recarbonized rising, second sample.	46·1	43·6	6·9	3·4

With the exception of No. 3, the gas of which approaches in composition that from basic steel, there does not appear to be any strongly-marked difference in the gas issuing from solid or from rising steel. It seems to be more a question of quantity, a point which Dr. MÜLLER promises to investigate. The analyses of steel cast previous to recarbonization naturally show a lower percentage of carbonic oxide, which, in open-hearth metal, is much higher, probably because the slow process of combustion of the carbon gives the steel a better opportunity to saturate with that gas; while, on the other hand, the cover of cinder on the bath prevents it from absorbing any great quantity of nitrogen and hydrogen.

Dr. MÜLLER'S most interesting results are those obtained with basic steel, where the gaseous products play a peculiar part. While the steel is comparatively quiet in the converter after the addition of spiegel, and ferro-manganese causes the formation of but little carbonic oxide, the escape of gas in the ladle is very violent. After it has been completely quieted in the ladle, it begins to agitate and scintillate in the ingot, and large quantities of gas escape from it until it is chilled. In spite of these phenomena, the tendency to rise is slight, and the most violently agitated steel generally yields pretty solid ingots. Mild basic steel, carrying from 0·05 to 0·10 carbon, 0·05 to 0·10 phosphorus, 0·45 to 0·55 manganese, and a trace of silicon, made by deoxidizing and recarbonizing with two per cent of 95 per cent ferro-manganese, yielded steel from which gas analyzed under Nos. 1 to 5 was obtained. Harder steel, 0·25 carbon, made with 8 per cent of spiegel, yielded No. 6, and a rail steel made with 10 per cent of spiegel gave two samples of gas taken from the fourth and the last ingot, nine minutes later.

ANALYSES OF GAS FROM BASIC STEEL.

	Carbonic oxide.	Hydrogen.	Nitrogen.	Carbonic acid.
1. Mild basic steel	61·3	2·3	36·4	0·0
2. " " "	57·5	4·7	38·0	0·0
3. " " "	76·6	6·1	17·3	0·0
4. " " "	50·9	5·1	43·3	0·3
5. " " "	77·3	6·4	16·0	0·4
6. Rail steel, 0·25 carbon	68·0	16·2	11·0	4·8
7. Rail steel, first sample	56·5	33·0	8·6	1·9
8. " " second sample.	62·0	34·2	1·0	2·8
9. Mild steel, first sample	77·9	5·7	14·7	1·7
10. " " last sample	62·6	12·6	23·2	1·6
11. Rail steel, first sample	81·7	8·2	9·5	0·6
12. " " last sample	54·1	38·6	3·5	3·8

As the escape of gas is particularly violent so long as the steel in the ingot is fluid, and decreases as it solidifies, Dr. MÜLLER took a sample after casting and when the ingot was setting, the results being given in Nos. 9 and 10 and 11 and 12. These analyses show that the frothing of the basic steel at first is due almost entirely to carbonic oxide, and that during the actual process of solidification the same gases escape as are taken from an ordinary Bessemer ingot. Particular interest, therefore, attaches to the examination of metal not recarbonized, whose contents of gas seem to vary considerably. The metal is often quiet and yields pretty solid ingots, and at other times it scintillates and rises considerably. Dr. MÜLLER believes that, if it is not too much over-blown, and if there is still 0·15 phosphorus in the bath, the metal without final additions yields a quiet ingot. No. 1 in the following table is a quiet steel, Nos. 2 and 3 two successive samples of a metal richer in gas:

GAS FROM BASIC METAL NOT RECARBONIZED.

	Carbonic oxide.	Hydrogen.	Nitrogen.	Carbonic acid.
1. Basic steel, quiet	8·8	71·9	18·1	2·0
2. Basic steel, rising, first sample	27·3	43·5	26·2	3·0
3. Basic steel, rising, second sample	35·0	38·4	22·5	4·1

It would appear, therefore, that, previous to the final addition, the gas in the metal does not differ materially from that in the unfinished steel of the acid converter.

In view of the importance of the Terre Noire method of making solid castings, which has been introduced in this country, the action of additions of silicide upon basic steel are of special interest. Two cases have already been referred to. An addition of five per cent of melted silicide and two and a half per cent of melted ferro-manganese produced steel that was quiet, but showed a tendency to rise. It was unfit for use, being cold-short. Analysis showed that the percentage of phosphorus had risen from 0·106 to 0·515, while silicon was only 0·011. The addition, it is true, quieted the steel, but the reduction of phosphorus was too great. In order to limit the latter, another charge was worked by adding 5 per cent of silicide and 2 per cent of 70 per cent ferro-manganese, simply preheated to a red heat, to the metal when in the ladle. Analysis showed the following:

	Carbon.	Silicon.	Manganese.	Phosphorus.
Before addition	0·002	0·002	0·083	0·078
After addition	0·115	0·162	0·944	0·097
Computed composition	0·140	0·530	1·250	....

The reduction of phosphorus was small only and the steel was quiet, but it rose and yielded unsound ingots. The gas escaping from the ingots in the two experiments had the following composition:

GAS FROM BASIC STEEL TREATED WITH SILICIDE.

	Carbonic oxide.	Hydrogen.	Nitrogen.	Carbonic acid.
1. Silicide added in converter, first sample	64·6	18·9	14·4	2·1
2. Silicide added in converter, second sample.	44·1	41·6	10·6	3·7
3. Silicide added in ladle, first sample	34·7	58·0	4·1	3·2
4. Silicide added in ladle, second sample	30·8	65·8	1·9	1·5

The experiments with silicide, while they certainly show the quieting effect of additions of silicon, do not prove that it leads to the making of solid metal.

Dr. MÜLLER concludes, from his analyses of the gas escaping from chilling steel of various grades and in different stages of manufacture, that the rising of steel is due to the escape of alloyed hydrogen, while the frothing and scintillating are the result of the escape of absorbed carbonic oxide gas chiefly. Basic metal previous to deoxidation and recarbonization contains chiefly hydrogen and nitrogen and little carbonic oxide, so tha

the metal when cast is quiet. As soon as spiegeleisen or ferro-manganese is added, carbonic oxide is formed in great quantity, the steel is saturated with the gas, which escapes partially in the ladle and partially while the steel is solidifying in the ingot. Other kinds of steel show a much larger proportion of hydrogen; but it might be thought, because the gas mixture escaping during solidification holds on an average about 30 per cent of carbonic oxide, that after solidification the contents of the blow-holes should show a similarly heavy percentage. Now, Dr. MÜLLER'S drillings have shown that, on the contrary, the gas in the blow-holes contains but little carbonic oxide, being a mixture of hydrogen and nitrogen. There is much force, therefore, in his conclusion that alloyed hydrogen escaping in the very act of solidification, in a manner similar to the crystallization of graphite in pig-iron, is the principal cause of the most dangerous form of porosity in steel, while carbonic oxide, which is expelled much more readily, is to be dreaded much less.

CORRESPONDENCE.

The Black Hills of Dakota.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: It is not a light undertaking to reach this land of gold and now of tin as well as other metals. The traveler must accept the discomforts of a stage ride of two days and two nights; for there is no railroad on the east nearer than Pierre, on the Missouri River, and on the south than Sidney, on the Union Pacific road. The first is 160 miles distant, and the second 250 miles; yet the residents of the Hills generally prefer the longer route by Sidney, as there is less discomfort from freight inside as well as outside the stages.

From Sidney, the route is directly north, crossing in succession the east and west valleys of the North or main Platte, the Niobrara, the White River, and the South Fork of the Cheyenne. The "Plains" between these valleys have a gently rolling surface, stretching away on all sides as far as the eye can reach, an unbroken field of green grass, waving in the wind, and tempting the scythe of the mower. The gama-grass is unusually green and fresh this season; for the rains have been frequent, and it has not been eaten down. There are no herds of buffalo as formerly, nor even of stock cattle; for at this time of the year, the cattle are chiefly along the bottom or valley lands. Now and then, a few frightened antelope may be seen fleeing across the hills, as the stage rolls along.

EROSION OF PLATTE VALLEY.

When the road reaches the margin of the Platte Valley, there is a sudden change of scene. The broad stretches of prairie are broken by ravines leading into the valley, which is here clearly seen to be cut out of the general level or slope of the plains. It is well marked by the line of bluffs on each side; the edges of the horizontal beds of rock projecting in white cliffs among the growth of stunted pines. Standing on the edge of this bluff formation, the valley lies some six hundred feet below, and is nearly twenty miles wide. The opposite side is seen to be similarly walled in by bluffs, and when in the valley it seems to be bordered by mountains. The river flows here in a broad gravelly bed, and though fordable by stock cattle when not swollen by floods, it is crossed by a bridge a mile in length, the approach to which on the north end is guarded by a block-house fort on an island.

The geologist can not cross this broad valley cut out of the plain without being impressed by the enormous amount of material which has been removed from the general slope of the plains by this river, and similarly by the other streams flowing from the Rocky Mountains. The miner, accustomed to make calculations of tons of ore in a given length of vein, is tempted here to calculate the weight of material moved into the Missouri and onward to the gulf; but here he must deal with cubic miles instead of feet or tons. The transfer of such an enormous amount of material is a factor not to be lost sight of in terrestrial dynamics.

The road crosses also the upper portion of the Bad Lands, where the phenomena of erosion are well shown, and where the beds of clay have yielded up some of the most interesting fossils known.

The first view of the Hills is not particularly impressive as respects hight. The ridges are long, low, and dark, owing to the pine forests which cover them; but the central ridge has an irregular, serrated outline, and portions of it are quite bare and gray. This is the Harney range, the backbone of the Hills. It is essentially granite, and it is flanked on each side by mica schists, which are in turn overlain by stratified formations, from the Potsdam sandstone up. All these have been well described in the report by Messrs. Newton and Jenney. The crystalline rocks now, however, become more than ever before interesting and important, inasmuch as

TIN ORE

has recently been found in them, and in such quantities as to justify mining it. About the first of June last, Capt. A. J. Simmons, of Rapid City, received from some miners who were prospecting for mica masses of very heavy brown ore. Samples were sent to Mr. Gashwiler, in San Francisco, and submitted to Prof. W. P. Blake, who determined the ore to be cassiterite or tin oxide of good quality. A ton or two of specimens have been taken out. Assays by Price and by Mollitor and others show a percentage of from 35 to 60 of metallic tin. The locality has been examined recently by Mr. Blake, who finds the ore not only in massive bunches in a coarse granite vein, but disseminated in grains through a peculiar micaceous rock, and in a condition to be easily separated from the rock by crushing and washing. Considerable stream-tin has also been found, and the prospect is, that a very considerable amount of tin will soon be produced in this region. The Hills have several advantages for tin mining. There is an abundance of water for concentrating-works and a profusion of wood for charcoal to use in smelting. As soon as the right of way is obtained from the Indians, two or more railroads will connect the Hills with the railroad system of the Missouri Valley, and thus give cheap transportation and other advantages.

GLÜCK AUF.

DEADWOOD, DAKOTA, July 30.

LAKE COPPER INTERESTS.

Special Correspondence of the Engineering and Mining Journal.

To the copper country your correspondent turned his steps a few days since, for a brief but pleasant pilgrimage. He found that the Huron had stopped hauling its rock across Portage Lake to the Pewabic stamps, and was now using its own mills, the economical but substantial construction of which reflects great credit on the mining superintendent, Mr. Johnson Vivian, who is now able to stamp rock as cheaply as any of his neighbors. In common with the Peninsula and Allouez, the Huron has now a bountiful supply of water for milling purposes, and, with its very complete equipment, has at last got a fair chance to demonstrate what it can do. The mine has not, in time past, made much headway in its cupriferous returns. It has worked nearly as many men as the Pewabic, while its mineral product has frequently been only about one third as great as that of its quondam benefactor. Its output for July was not far from twenty tons. Now that the Pewabic is free from its contracts to stamp the Huron ground, it will put in both shifts (two of its Ball heads instead of three, however) on rock hoisted from its own shaft. And this is quite opportune; for, while it must be acknowledged that the monthly average for the first half of 1883 is below the last half of 1882, yet it now looks as if the famous lean stretch is being left behind the present bottom levels, and that the mill will yet be needed at full capacity to deal with the profitable rock of the future. The Pewabic lowers its June record by about four tons in July, making an exhibit for the latter month of 64¼ tons. The Pewabic has also been retarded by the necessity of using its skip for unwatering the mine; but adequate pumping facilities are now put in, and the skip will henceforth be devoted to its legitimate business. The bears may take another bite at this property when the next assessment is called in; but if the present outlook of the mine is not deceiving, and if copper hardens any under the pressure of London speculation, an ultimate and satisfactory rise in Pewabic may safely be taken as a foregone conclusion.

This leads to the remark that the future of copper is still problematical, despite the very satisfactory movement of mineral across the water, and is likely to remain so for some little time. The two or three London gentlemen who have heretofore manipulated the market in tin, and autocratically determined its price in both hemispheres, will find it dangerous to attempt a corner in copper, particularly when our Western mines are sending their products out with so much energy to foreign markets. I notice that the London *Iron Monger*, in a recent and careful estimate concerning the total American supply for 1883, corroborates in all its details the figures arrived at in my independent calculation made in May, and published in the ENGINEERING AND MINING JOURNAL of June 2d. For the sake of accuracy, it ought to be said that both the *Iron Monger* and your correspondent were a little high on the amount left over from 1882, as I now know indirectly from the Eastern syndicate which holds the exact figures of the matter in hand, and which figures are secret. This simply gives lee-room for confidence in my estimate of 72,000,000 pounds as the consumption of 1883, but in no respect lessens the quality of the deductions of my ancient letter. It is not altogether ungratifying that the present outlook should fulfill, in such minute details, the position at which your correspondent arrived in the early months of the calendar year. After a careful study of the facts as they were presented in my letter of June 2d, the total American production for 1883 was placed at 147,000,000 pounds. From a very careful computation, "Refiner," in his letter of August 11th, states that the total product will be 145,000,000 pounds. But this is on a basis of 55,000,000 as the output of the lake mines. This, I am convinced, is wrong. "Refiner" bases his calculations on the reports of the leading mines for June only, while, for the first six months—more, the first seven months—the output of each one of the five largest reporting mines, together with the Osceola, which has not reported, has presented an increase which in the aggregate amounts to not less than 800,000 pounds, at which rate (and it will not fall below it, since the Calumet & Hecla is somewhat handicapped by changing its plant of stamps and Leavitt patterns), it will certainly not fall below 1,500,000 pounds increase for the twelve months of this year. The Pewabic, Grand Portage, and Conglomerate have fallen off a trifle (the last having suspended milling operations until the completion of the new stamps at Lac la Belle); but the Copper Falls, Huron, and Central have, as a whole, gained in higher ratio, while the Peninsula and Wolverine have already sent out 1,000,000 pounds, and in future operations will raise their own record by a very comforting trifle.

The figures already advanced will raise "Refiner's" figures to my own, and thenceforth our reasoning is parallel. Your correspondent now puts the output of Lake Superior at 59,500,000 pounds, though it may fall short by half a million—certainly not more. After all is told, it is safe to say that, after the home demand is supplied, there will be 75,000,000 pounds yet waiting, which your correspondent said must be carried over as the crushing incubus on the trade of 1884, or have the gates lifted which open into foreign seas. This latter has been done; 30,000,000 pounds have already found a market there, and, if prices stay up, 10,000,000 more, says "Refiner," must go. This is all your correspondent ever set out to prove; and in their essential points, at least, the figures of June 2d may, he modestly thinks, be taken as foregone conclusions. If, therefore, the London syndicate can corner the market, or is even able to dictate prices to any extent, the price of several lake mines will vault into higher planes, and the land of dividends, which now seemeth afar off, will suddenly draw nigh. The uncertainty lies in our exports, and a Damocles sword may cut that escape off, if the syndicate, failing to be sanguine of accomplishing its purposes (when the possibilities of the Montana and

Digitized by Google

Arizona mines are taken into account, to say nothing of the Spanish mines, which have exhaustless reserves already opened), should once begin to unload on the market. This brings us back from our interpolated meandering to the Pewabic.

From what data are just now accessible, the price of stock in reputable iron mines has suffered little collapse on account of the glut in iron, and it is passing strange that such a calamity should overtake the Pewabic, which once sold for over fifty dollars, and which now has every appearance of sinking into rich areas. However, the small number of shares that have changed hands among Portage people shows that the stockholders here intend to stand by the mine, and the entire sentiment of the best miners, as far as your correspondent could get at it, is, that a revival warranted by the facts will set in in Pewabic in the not distant future. But this, of course, is provisional, and, like all other prophecies where bulls and bears gore and hug, must not be taken for more than it is worth. The Franklin is truly looking well underground, is increasingly regular in its productiveness, and is remarkably cheap at present rulings. The record for the first six months shows a marked advance over the splendid returns of 1882, and over 350,000 pounds over the first six months of 1881. The Grand Portage is not trying to do very much, and is succeeding very well in its undertaking. Another of the smaller mines is straining at a gnat hard enough to swallow a camel; but these efforts only facilitate the disease which threatens to carry off the patient, provided, of course, no stimulant in the way of an assessment is handed in by those interested in the survival of the concern. The Quincy is clearing the way for a new boiler-house at the mill. It lately completed a new dock, which forms an excellent bulkhead against the discharge of its sand into the lake, and which is a material advantage to the shipping facilities of the harbor.

Let me observe, *en passant*, that the sand deposited as "tailings" from the stamp-mills is a matter which may well receive attention from the next Congress, since Portage Lake is a national highway, and the encroachments of the tailings, particularly from the Franklin mills, have pushed their way nearly if not quite half-way across the lake. There is no immediate danger to navigation, and proper caution will obviate any danger for the next generation. The report of Messrs. Schermerhorn and Roberts, of the Engineer Corps of the United States, estimates the amount of sand discharged into Portage Lake as being in excess of 3,500,000 cubic yards. This report shows that the "tailings" are a formidable matter, and ought to be regulated by a power superior to and independent of the mining corporations. A spirit of petty jealousy threatened to make the discharge of the Franklin stamps the entering-wedge of a serious controversy; but a quietus was administered an officious official, and the location of this bank as the site of a draw railroad bridge will remove from the Franklin the possible incubus of a serious litigation and obstruction. Next week, we shall start overland for the mines of Keweenaw, and by water for those of Ontonagon.

SPECULAR.

THE FRISBIE CLUTCH AND ITS USE IN HOISTING-ENGINES.

Clutches of various forms are gaining in favor, as applied to hoisting-engines, for a large variety of purposes. Among those which have of late been introduced in connection with mine hoisting is the clutch designed by Messrs. D. Frisbie & Co., of Philadelphia. The leading features of its construction may, in a general way, be best described by references to the cut-off coupling shown in Fig. 1, the modifications used for hoisting-engines embracing only such minor changes as are called for by the exigencies of each special case. On the driving-shaft on the right in our figure, is mounted a sleeve, the motion of which is, by the compound levers shown, transmitted to the bevel-headed bolts, held in position by an arm keyed to the shaft. If, through the pressure exerted by the position of the compound lever, the sides of the bolt-head are forced against the V groove, the other shaft is carried along. As the length of each bolt is adjustable by means of the nut, each single one can be adjusted to suit the load, while the power of the clutch is illustrated by the fact that a twenty-eight inch clutch, said to be the largest in use in this country, has been used to move 90 tons on the Harlem River drawbridge.

The application of the Frisbie clutch to hoisting-engines is shown by the sketch, Fig. 2, which is a horizontal section through a drum driven by belt, though, of course for longer distances wire rope is substituted. One end face of the drum carries the V groove, against which the bevel-heads of the bolts are pressed through the action of the levers, the projecting ends of which slide along the inclined surface of the cone when the latter is moved toward the drum by means of the simple lever shown. The drum of course moves freely when the clutch is off, and may be held in any position desired, by a brake. An end view of the machine is shown in Fig. 3, in which only one arm and bolt are drawn, to prove that the friction surface is large and can be easily adjusted. The Frisbie clutch is now applied on drums at Lake Superior copper mines and in Leadville mines.

THE SMELTING OF ARGENTIFEROUS LEAD IN THE FAR WEST.*

By O. H. Hahn.

Early Attempts.—Twenty years ago, the smelting of argentiferous lead ores was an unknown thing in the far West, under which collective name the States and territories west of the Mississippi River are generally known; and although there were persons to be found in the mining districts who were familiar with the methods of smelting current in European countries, the first attempts in this branch of the metallurgical industry were failures, because the appliances used and the grade of the ores to be treated were not adapted to the requirements of the localities of that vast yet sparsely settled stretch of country, then entirely devoid of cheap transportation facilities. Who would ever think nowadays of building a Flintshire or a Carinthian furnace, or a Scotch hearth, or a Mexican "chacuaco" in the wilds of Nevada or in the Rocky Mountains, to smelt lead ores? Yet such was the apparatus first resorted to in the beginning of our smelting industry, evidences of which may still be found in the ruins of Galena (Washoe County) and Washington districts, Nevada; in the Patagonia Mountains of Arizona; in Little Cottonwood and Rush Valley, Utah; Cerro Gordo, California; and other localities. It seems that the early smelters did not calculate the cost of their product, or imagined that they were operating on the sea-coast, where fuel, labor, and every thing else are cheapest.

The first smelting-works with an appearance of success sprang up near Helena, Montana, and at Oreana, Nevada, a station on the line of the Central Pacific Railroad, in 1866 or 1867. In both places, the ore treated had a sufficiently high silver tenor to leave a margin over and above the cost of working it and the expense of transportation of the silver, which is no small matter, if we consider that not only had the ores to be smelted, but the resulting bullion had to be calcined and cupelled on the spot to obtain the silver in salable shape. For the lead, or litharge rather, there was no market in those days, all wants being supplied more cheaply by the Missouri and European producers. The year 1869, when the two great Pacific railroads were united to form an uninterrupted line of communication between San Francisco and New York, the great commercial centers of the East and West, gave the signal for the beginning of smelting operations on a more extensive scale than heretofore, and for the gradual expulsion of foreign lead from our markets. Till then, mines producing "cooking ores," as lead ores were scornfully termed at that time, did not find ready purchasers, especially as those ores generally occurred in limestone formations, which were then considered as very unreliable ore producers. But the success of the firm of Buel & Bateman, who had bonded the mines now known under the name of the Eureka Consolidated, and who turned a perfect stream of rich bullion from two small furnaces on to Balbach's refinery at Newark, New Jersey, wrought a sudden change. Lead mines, good, bad, or indifferent—but "true fissure-veins" they must of necessity be—were at a premium, and smelting-works sprang up like wild-fire everywhere. The nucleus of excitement, however, centered about Salt Lake City, whose neighboring mountains were known, from the explorations of the Mormons and the soldiers of General Conner, to teem with lead ores. The comparative poverty of the ores in silver, their siliceous and frequently refractory character, the close competition in their purchase, the bad quality of the fuel and furnace lining, and a good many other things, sharpened the intelligence of the Salt Lake Valley smelters, more so than that of others; and it is to them that we owe the introduction of improvements which led to a more economic handling of the ores. Iron ore and limestone were here used intelligently as fluxing material for the first time; Connellsville coke superseded, at least partially, the miserable charcoal which was made from the light woods of Utah; water-jackets replaced the out-walls as well as the costly fire-brick lining of the furnaces; dust-chambers were erected to save the escaping finest particles of ore; and a number of very complete sampling-works were erected, which opened a liberal market to the miner and afforded the smelter an opportunity to select for purchase such ores as suited his wants. It is true, Eureka, Nevada, has been, so to speak, the cradle of the art of smelting in the West; to Arents we owe the introduction of the siphon tap, the construction of the first large and successful furnaces, and the reintroduction of the boshes in lead furnaces; but beyond these, Eureka does not offer any innovations in the smelting process itself. The same routine is observed there as of old. The principal reasons for this conservatism are, first, the docile character of the predominant ore (of Ruby Hill), which requires little or no flux to give economically satisfactory results; and, secondly, the fact that mines and smelters of the leading companies are managed by the same person, generally a miner or a business man who is reluctant on general principles to adopt improvements of a scientific nature.

Recent Progress.—In localities where mines and reduction-works are not united under one head, and where, on the contrary, the miner sells his product to the smelter who pays him the most money, there is no room for nursing prejudices. Business, art, and science have to go peaceably together; and it is owing to the co-operation of these three factors that we are progressing day by day in search for the most profitable methods in the art of smelting.

Silica Percentage of Slags.—It is taught in the mining schools that in smelting lead ores the object is to make a singulo-silicate slag, or one between this and a bisilicate, of the earthy matter in the ore, which best enables us to effect its separation from the metallic matter; it is also taught that simple singulo-silicates are not as easily fusible as compounds of two or more singulo-silicates; for instance, a compound of the singulo-silicate of ferrous oxide with that of calcic oxide. It was further known in practice for a long time that if, in fluxing an ore, the proportion of lime to oxide of iron is kept as one part of the former to two parts of the latter, a good slag would be the result; that is, one which will form with the least amount of fuel, keep the furnace open, and be free from lead and silver. But, with all this knowledge, more bad slags than good ones were made, till several thinkers were led to the right track by giving their attention to crystallized slags, which presumably are real chemical compounds, and therefore have a constant composition, while amorphous slags might be considered as mere mixtures of different silicates or solutions of one silicate in another. It was observed that some crystallized slags behaved better than others in the furnace. If such a slag, then, could be made at will, a great problem was solved; any kind of ore could be smelted without the least trouble by giving it the lacking constituents in the same ratio as they are found in the analyzed slag. This necessitates, of course, an accurate knowledge of the slag-constituting ingredients of ore, fluxes, and ash of the fuel, which can only be arrived at by chemical analysis and an accurate weighing of all the material into the furnace. Taking all these precautions, a slag of the same crystallization as the typical one will almost invariably result, other things being equal. I say "almost invariably," because oxide of zinc seems to prevent crystallization; at least, such was my experience in Colorado. The slag-forming matter of an ore which has to be most frequently dealt with in lead smelting consists of the following substances:

1. Silica.
2. Alumina.
3. The oxides of iron and manganese.
4. Lime and magnesia.

Baryta and strontia are of rarer occurrence, and the oxides of the alka-

* From advance-sheets of *The Mineral Resources of the United States*, published by the United States Geological Survey, Department of Industrial Statistics. Albert Williams, Jr., Chief of Department.

Digitized by Google

line metals exist only in such subordinate quantities that they may be neglected.

All the above-named substances are hardly ever found present in the same gangue, and much less arranged in such a proportion as to yield at once a suitable slag in smelting. By supplying the ore with the deficient ingredient, we *flux* it and form a "smelting mixture." According to the amount of combined silica present in a slag, we distinguish three degrees of acidity:

1. Subsilicates, in which the oxygen of the bases is to the oxygen of the acid as 2:1—

$$4RO+SiO_2=R_4SiO_6 \text{ ; or } R_2O_3+SiO_2=R_2SiO_5.$$

2. Singulo-silicates, in which the oxygen of the bases is to the oxygen of the acid as 1:1—

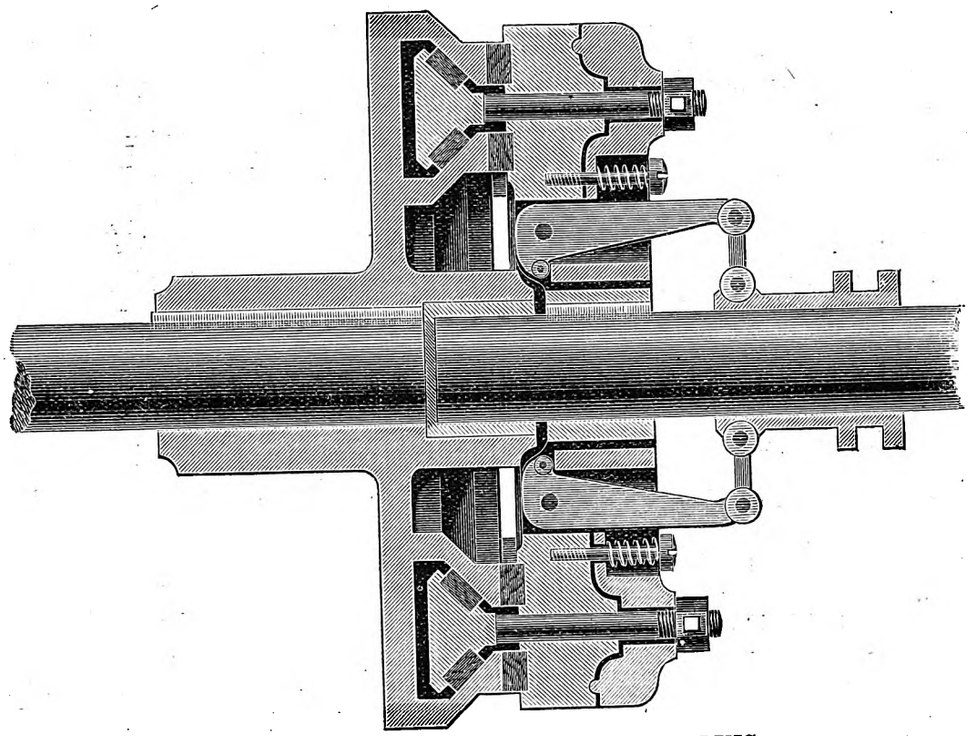
$$2RO+SiO_2=R_2SiO_4 \text{ ; or } 2R_2O_3+3SiO_2=R_4Si_3O_{12}.$$

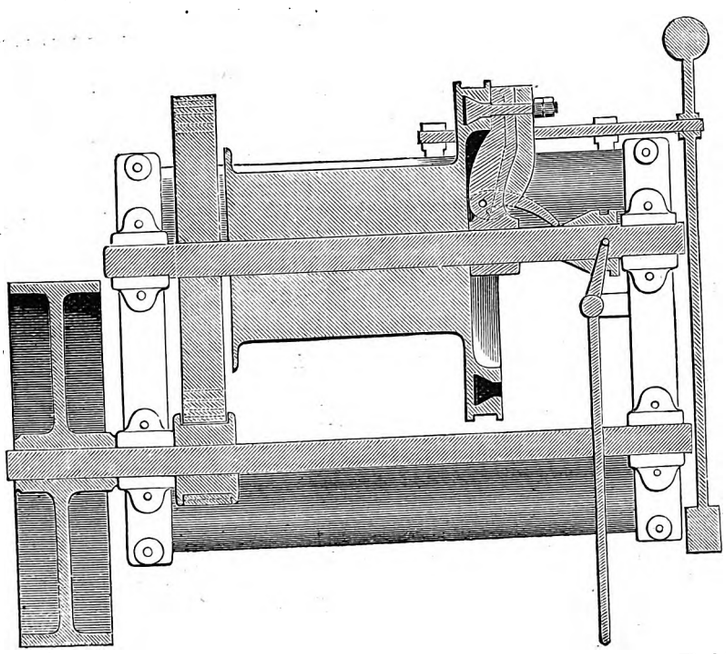
3. Bisilicates, in which the oxygen of the bases is to the oxygen of the acid as 1:2—

$$RO+SiO_2=RSiO_3 \text{ ; or } R_2O_3+3SiO_2=R_2Si_3O_9.$$

Subsilicate Slags.—The subsilicates are not made at present, at least not intentionally, on account of their evil behavior; but they are mentioned because they may be used as a flux on account of their capability to saturate themselves with silica. The subsilicates of alumina and those of the oxides of the alkaline earth metals are infusible; but the subsilicate of iron is very easily fusible, and at a lower temperature than singulo-silicates. It has a high specific gravity, runs very thin, solidifies very rapidly, and has a bluish metallic luster and fine-grained texture. It forms accretions in the furnace hearth, causes the furnace to blaze, and entangles metallic particles. It also has a highly corrosive action on the masonry of the furnace.

Bisilicate Slags.—Bisilicates are not made in this country, to my knowledge, except unintentionally, as there are no furnaces of sufficient hight to make them without evil results. Those highly siliciferous slags, which Mr. A. F. Schneider describes in Vol. XXXIV., page 283, of the ENGINEERING AND MINING JOURNAL, are still singulo-silicates, because the combined oxygen of all their bases is to that of the silicic acid as 1:1. Bisilicates have a glassy flow and generally a black color, and do not *often* crystallize, as we glean from the latest metallurgical publication (Balling's *Compendium der Metallurgischen Chemie*). It appears from analyses quoted in metallurgical books that they always carry considerable oxide of lead, which is probably due to their faulty composition. A typical one of the form $6FeO,3SiO_2+4CaO,2SiO_2$, in which the percentage proportion of oxide of calcium is to protoxide of iron as 1:2, has been the most interesting slag to the lead smelter is the *singulo-silicate.*





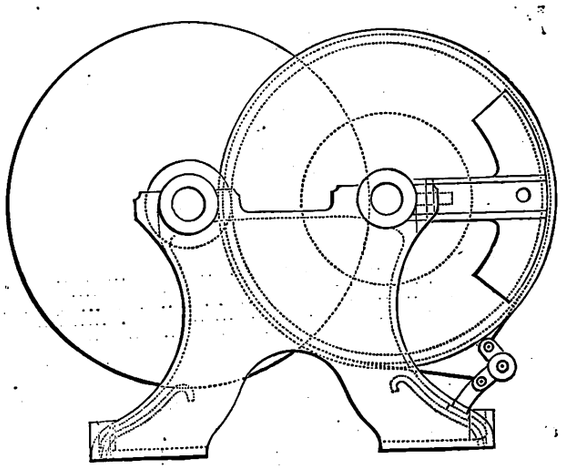


Fig. 1. THE FRISBIE CUT-OFF COUPLING.

Figs. 2 and 3. THE FRISBIE CLUTCH AS APPLIED TO A HOISTING-DRUM.

Digitized by Google

long known, and has nevertheless not been often made, if we may judge by the analyses published in metallurgical papers, until Mr. A. Eilers, and probably a few other metallurgists, recognized its great virtues. This is a most magnificent slag; its physical appearance in the slag-pot is so marked that one who has once seen will never forget it. If the proper amount of fuel has been given to the charge, it will contain neither lead nor silver; and it is my opinion that if it ever is metalliferous it is through small globules of matte dissolved in it, which have not been separated on account of lack of heat in the furnace. Running on such a slag, a furnace can never get out of order except through gross carelessness. It is, however, the duty of the metallurgist to correct the slag if it shows imperfections; for instance, if it shows an excess of iron, a lack of silica, etc. An addition or a reduction of a few pounds of one flux or the other will show itself in the appearance of the new slag as soon as it gets down to the hearth. This explains why, in throwing the charge into the furnace by volume, and not by weight—the old "shovel system"—a typical slag (that is, one of a fixed composition) can not be obtained. Each pot of slag running out of the furnace will differ from the preceding one; and if the furnace becomes deranged, it may be impossible to perceive what caused the trouble. On breaking a cake or cone of slag as it comes out of the pot, after cooling, it will show cavities filled with large crystals. Unfortunately, they are never entirely developed, so that one can be able to determine to which crystallographic system they belong.

Various Slag Components.—Heretofore, we have assumed that a slag is only composed of silica, iron, and lime. An ore or a flux may, however, contain notable quantities of other substances which would play an important part in the formation of a slag, such as manganese, magnesia, etc. Experience has shown that manganese acts analogously to its related metal, iron; magnesia, baryta, and strontia to lime. In the case of alumina, we have to make the slag more acid by an amount of silica corresponding to the alumina, according to the formula of a singulo-silicate, namely, $2Al_2O_3.3SiO_2$; otherwise, we should obtain too basic a slag. It is obvious that a slag of the above composition, needing so much lime, would make the treatment of some kinds of ore, such as carry much ferruginous or manganous matter, very expensive, inasmuch as it reduces the percentage of ore in the smelting charge very considerably. This point occupied the attention of Mr. Eilers while treating the ferruginous ores of the Flagstaff mine in Utah; and after much labor and many sleepless nights, he succeeded in making a slag which very nearly corresponds to the formula,

$$6FeO,3SiO_2+2CaO,SiO_2,$$

and in which the proportion of calcic oxide is to ferrous oxide as 1 : 4. The physical appearance of this slag is still more striking than that of the first one; it is simply beautiful, and it crystallizes also, but in a different system. It has a black color, frequently with a rusty brown film, and a fibrous texture. It fills all the requirements of a good slag, metallurgically as well as commercially, but it is not quite as free from lead oxide and silver as the former. It keeps the furnace open (that is, free from hearth accretions), and is especially adapted for smelting ores containing a large percentage of zinc, this greatest enemy of the lead smelter. Oxide of zinc makes a slag difficult to fuse, and silicate of zinc is infusible; but both dissolve readily in an excess of the slag just described, while the more calcic slag becomes much less fluid. In other words, ferrous oxide increases the liquidity of zinciferous matter, while lime decreases it.

If the proportion of ferrous oxide is raised beyond the limits just given, but at the same time the degree of acidity corresponding to a singulo-silicate is maintained, the remarkable fact is observed that the slag becomes rich in lead oxide. In consequence of this, its physical appearance changes entirely. It shows a blueish hue and waxy luster in its fracture, runs like stearine, and forms hard accretions in the furnace-hearth. This slag was formerly made at some works in Leadville, at which the necessity of using lime in their smelting mixtures was decried, and thus a great waste in lead and silver resulted.

The lack of iron in the Utah ores, and the great cost of iron flux as compared with limestone, induced prominent Utah smelters to search for a type of slag in which the proportion between lime and protoxide of iron is greater than one of the former to two of the latter, and they seem to have succeeded very well. I have seen a sample from the Horn-Silver works which had a color like stove polish, a greasy luster, and well-formed crystals in its cavities. Schneider gives its percentage composition as follows:

SiO_2	35
FeO	25
CaO	26
Al_2O_3	10
Not determined	4
	100

This would respond to the formula,

$$6FeO,3SiO_2+8CaO,4SiO_2+2Al_2O_3,3SiO_2.$$

As will be observed, there is a large amount of alumina in this slag; and it might, therefore, be questioned whether such a slag could be made if alumina were lacking.

Estimation of Slags.—In the early stage of smelting at Leadville, great difficulties were encountered at most of the works in making a good slag, and the "muscular" method had to be frequently resorted to in freeing the furnaces from sows. This evil was in great part due to disregarding the alumina contained in the ore; and also to the manganese, which was not regularly determined on account of the tedious methods then in use. The result of this oversight was a very basic slag, which would naturally close up the furnaces. Mr. T. Macfarlane, in a paper read before the American Institute of Mining Engineers, suggested that, by determining the specific gravity of a slag, a clue might be obtained for improving it if not correct. If the specific gravity were higher than that of the typical slag, this would prove an excess of the bases of the heavy metals in the faulty one. But whether it required an addition of silica, or of lime, or of both, the determination of the specific gravity could not tell us. In the case of a slag which is far out of the way, correct chemical analysis alone, however tardy it may be, can give us information. Since the introduction of more rapid volumetric methods for the determination of manganese (for example, Guyard's), and the estimation of the alumina in slag computations, all troubles of this nature have ceased.

A fact to which Dr. Iles, of the Grant Smelting-Works, now at Denver, first called attention, and which it appears might be turned to account in correcting a slag, is the behavior of its powder under the magnet. Some slags are highly magnetic, while others are not. Would this not indicate that magnetic oxide is dissolved in the slag, which has escaped reduction to ferrous oxide, and thus causes a waste of precious flux?

Elimination of Sulphur, Arsenic, Antimony, etc.—The subject of slags has been dwelt upon at some length, because the metallurgical success of smelting depends in a great measure upon their composition, and it may be said *altogether* in the case of cerussite ores. But as soon as sulphur, arsenic, antimony, and other electro-negative elements enter into the composition of an ore, this alters the case; we have to eliminate them in some other manner before we can extract the pure lead without difficulty. There are two ways of doing this:

1. By precipitation by means of metallic iron.
2. By roasting the ore.

Precipitation by Iron.—The iron-precipitation process is only applicable to galena ores and lead ores contaminated with small quantities of the sulphides, arsenides, and antimonides of other metals, to which should be added all sulphates, arseniates, and antimoniates, as they are reduced in the furnace to sulphides, arsenides, etc.

This process is based upon the fact that iron has a greater affinity for the electro-negative elements than lead and silver. If, therefore, iron is brought in contact with molten sulphide of lead or silver, it will, as soon as it has acquired the proper temperature, combine with the sulphur, while lead and silver are set free as reguline metals. The affinity of silver to sulphur is, however, stronger than that of lead, which is the reason why some sulphide of silver is undecomposed, remaining with the sulphide of iron.

The compound of iron and sulphur is metallurgically called a *matte*, while that of iron and arsenic or antimony is termed *speiss*. The latter has a higher specific gravity than the former, which is the reason why, if both are produced during a smelting operation, the matte floats on top of the speiss. The mattes retain more silver than the speisses, while with gold the case is exactly the reverse. Lead enters the speiss only in the metallic state in the form of shots, while in matte it will be present as sulphide. Copper enters into either as sulphide and arsenide respectively, as it has a strong affinity for both sulphur and arsenic.

The iron may be present in a matte either as diferrous sulphide (Fe_2S) or as ferrous sulphide (FeS), but never as ferric disulphide (FeS_2), because the latter, on being exposed to a strong heat, is decomposed into magnetic sulphide and free sulphur. The former does not fuse well; it is mushy and liable to chill in the furnace, thus forming an accretion. It is therefore well to aim at making ferrous sulphide (FeS) in computing a charge. If copper be present in a lead ore, it will go into the matte as cuprous sulphide (Cu_2S). On the strong affinity of copper for sulphur is based its separation from lead. Iron and other heavy metals combine with arsenic in a great many proportions, according to the statements of metallurgical authors, who speak of

$$R_2As,R_3As,R_4As,R_5As, \ldots\ldots R_nAs.$$

Yet experience has taught the practical smelter that only crystalline speisses of a bloomy texture, similar to that of spiegeleisen, from R_5As toward R_nAs, will work well in the blast-furnace. Speisses from R_4As on toward R_2As run very thick, if at all, and form hard accretions (speiss sows) in the furnace. They are fine-grained, and always contain entangled metallic lead. An addition of metallic iron will therefore improve the liquidity of a speiss. How far we can go in augmenting the proportion of iron to arsenic, I am unable to state from my own experience; yet it may be surmised that an excess of iron in a speiss may be just as injurious to the operation of a furnace as an excess of arsenic.

Purely antimonial speisses have never come under my observation, so I can not say any thing about them.

Form in which Iron is used.—As it is not easy to obtain metallic iron in every locality, and as it is generally not in a proper shape for being weighed out and mixed accurately with ore and fluxes, it is preferable to supply the iron as a desulphurizer in its nascent state, in which it can be obtained by using a properly constructed furnace and making a slag of sufficient acidity, at the same time adding so much ferruginous matter to the smelting mixture as will correspond to the amount of metallic iron required for the saturation of sulphur, arsenic, etc. Furnaces with straight walls from top to bottom are poor reducers, while those provided with boshes operate very well indeed. Basic slags are not good reducers either, because they form at a temperature at which iron is not reduced; they will therefore merely mechanically dissolve the magnetic oxide which forms out of the additional ferruginous matter in the upper part of the furnace.

From the preceding remarks, it may be inferred that this process is not a perfect one, because it gives rise to the formation of intermediate or by-products which contain gold, silver, and lead. If thrown away, these metals will be lost entirely. If we wish to extract them, additional processes will have to be resorted to, and then the question arises, Will it pay? It is therefore advisable to subject only such ores to the iron-precipitation process as contain a minimum of sulphur, etc. What the maximum should be, can be determined by the local price of the iron flux compared with the cost of roasting.

The Roasting Process.—By roasting an ore, we wish to expel its sulphur, arsenic, or antimony, and convert the metals in it into oxides, in which form they are best adapted either to be carried into the slag or into the metallic state during the subsequent smelting. The roasting is carried out by exposing the ore to the action of heat and air, in consequence of which sulphur, arsenic, and antimony are volatilized as sulphurous, arsenious, and antimonious anhydrides, respectively, while the metals remain in the oxidized state. According to the apparatus in which the operation is performed, the result will be more or less complete. The roasting of arsenical and antimonial ores is rendered more difficult by the simultaneous formation of arsenic and antimonic acid, which combine with the metals to form arseniates and antimoniates. These compounds can only be decomposed by repeated additions of carbon and access of air, whereby the arsenic and antimonic acid are reduced to their arsenious and antimonious anhydrides and thus gradually volatilized.

Ores containing sulphide of zinc (zinc-blende, sphalerite) are also difficult to desulphurize by roasting, inasmuch as zincic sulphate is always

Digitized by Google

forming, which is only completely decomposed in a white heat. Mr. Stetefeldt found that sulphate of zinc is the most constant compound in the fire next to sulphate of manganese. While during the first two hours of roasting nearly all the sulphate of iron had been decomposed, there was still a large percentage of zincic sulphate undecomposed at the ninth hour. This behavior of zinc makes zinciferous ores difficult to work. In the blast-furnace, any sulphate of zinc remaining undecomposed after roasting will be reduced again to sulphide. This substance goes partially into the matte, if any is forming, partially into the slag, which it makes thick and stiff; it also carries silver along, and thus gives rise to losses above and beyond those inherent in all metallurgical processes.

Roasting-Furnaces.—With regard to the apparatus used for roasting, preference is given in this country to reverberatories, ranging from 30 to 40 feet in length and from 10 to 12 feet span, divided into four or five hearths. This arrangement admits of keeping four or five charges in the furnace, in as many different stages of treatment. As soon as one charge is drawn, all the preceding ones are moved forward one by one, and a fresh charge is put in. The time of roasting varies with the amount of sulphur in the ore, the bulk of the charge, the quality of the fuel, and also with the altitude of the locality above the sea-level. The size of the ore has a great influence upon the completeness of the desulphurization, and the more zinc-blende there is in it the finer it should be. At Robinson, Colorado, for instance, the ores could not be crushed finer than walnut size; and although a charge of 1300 pounds remained in the furnace for thirty-six hours, there was still from 7 to 8 per cent of sulphur left in the ore. The ore being highly zinciferous (21 per cent ZnS), the slag resulting from smelting contained considerable silver. From Przibram, Bohemia, it is reported that blende ores have been roasted down to one per cent sulphur.

If copper is present in an ore, there should be sufficient sulphur left in the charge to get rid of it as matte; otherwise, it will deteriorate the quality of the lead or be lost in the slag. Galena ores almost free from other sulphides roast better in a short furnace than in a long one, especially if the fuel does not yield a long flame.

For subsequent smelting, it is more convenient to have the ore in lump shape than in powder. Wherever, therefore, it is practicable, as in the case of ores with a large percentage of lead, to slag the ore, in other words, to convert it into silicates, it should be done. This slag should be drawn, and after cooling broken up into lumps of suitable size. As zinciferous and ferruginous ores can not be slagged very easily, it will be sufficient to sinter or "agglomerate" them.

Wood is used as fuel in places where its abundance makes it cheaper than stone coal, and it is preferable when it is of a resinous character. Mineral coal is, however, preferable to oak, mahogany, mesquite, or the lighter woods.

Matte Roasting.—In the foregoing outline, it has been observed that, whenever there is any sulphur in a smelting mixture, it has to be saturated with the necessary quantity of iron to form a matte of the right composition. To extract the lead and silver which these mattes retain, it is necessary to roast or calcine, and afterward flux and smelt them exactly in the same manner as an ore. If they are so poor in lead that there is danger of its being kept entangled in the slag and thus lost, it is advisable to add plumbiferous ores or products in sufficient quantity to effect a complete separation of lead and slag in the furnace. A charge containing 10 per cent of lead will be safe to answer this purpose, yet it is possible to obtain the same result with as little as 6 per cent. The question now arises, Will it pay to roast matte in a reverberatory, as it costs something to reduce it to powder besides the roasting itself? If the matte is rich in silver, it does; if not, then it requires close figuring of all expenses. I have known localities where poor matte was roasted in heaps. The only preparations it needed were coarse crushing, a bedding of wood to pile it on, and setting it on fire. The crushing is easy enough after it has been exposed for a while to atmospheric influences, which cause it to crumble. But the calcination is extremely tedious, as it will burn for a month or more, and then the whole pile will have to be turned over to assort the well-calcined stuff from the half-calcined and crude matte, from which a new pile or heap has to be formed. These manipulations have to be repeated till no more crude matte is left, and it will take months before that result is achieved. However well this matte may be roasted in heaps, it will always contain from 7 to 8 per cent of sulphur, which in the following smelting operation will cause another matte to be formed. It appears to me that this mode of roasting is not worthy of imitation in a progressive country where time is an object, and I find that most smelters take the same view. They are simply laying aside the poor mattes for a time when these may be reduced more cheaply and quickly than at present.

Attempts to roast ore in this manner have been frequently made, but just as often discarded as tedious and imperfect. An ore which does not bear the expenses of roasting in a reverberatory furnace should be left alone.

During the past year, experiments have been made at the Germania works, near Salt Lake City, to calcine mattes in an Unterharz kiln, but with what result I am not informed.

(TO BE CONTINUED.)

PUBLIC LAND SALE.—The Commissioner of the General Land-Office has been informed that the Register of the Land-Office of the St. Cloud District, Minnesota, began, August 20th, the sale of 2,000,000 acres of public land at auction. The price realized was $3.35 per acre.

An exchange says: Twenty-one miles of new road are to be constructed on the Seattle & Tacoma, and the work is well under way. From Tacoma to Seattle by this route, the distance is forty-one miles. The Puyallup extension from Tacoma, commonly known as "the coal road," will be used for ten miles, and ten miles of the coal road from Seattle to Black River will also be utilized; so that the total length of new road (from track to track of old roads) will be as above stated. Much trestle-work is required on this line—four or five miles in all—besides bridges across Black, White, Stuck, and Puyallup rivers. The Black River bridge will be a single span of 160 feet; that over White River, a single span of 180 feet; and those over the Stuck and Puyallup, respectively 160 and 320 feet. It is confidently expected that the road will be finished before the first of September.

THE DIVINING-ROD.*

By Rossiter W. Raymond, Ph.D., New York City.

(*Concluded from page* 81.)

Numerous hydroscopes soon appeared in Italy, and a vigorous discussion of the subject followed. One of the latest celebrated experts of this class was Campetti, who was called to Munich in 1806 for scientific examination. One of the writers of this period, the Abbé Amoretti, himself a member of a family containing many hydroscopes, makes the significant assertion that the sensation experienced by the holder of the divining-rod is one of heat or cold. But the name of Amoretti recalls the fact that he was one of those who revived and continued the discussion of "the magic pendulum."

The earliest mention of this apparatus, according to M. Chevreul, is found in the work of Ammianus Marcellinus, the last of the Latin historians, who died A.D. 390. In an obscure passage (lib. xxix., cap. 1), giving the confession of one of the conspirators against the Emperor of the East, this author describes, in the words of the conspirator, the ceremonies adopted by the band to discover the name of the emperor's predestined successor. Among these was the use of a ring suspended by a fine thread over a disk, around the edge of which, at equal intervals, were the letters of the alphabet. The ring in its oscillations pointed out successively the letters T, H, E, O: whereupon, without further continuing the inquiry, all perceived that Theodorus was the one designated by destiny.

Father Schott mentions the pendulum in his *Physica Curiosa* (1662), already alluded to in this paper.

In the latter part of the eighteenth century, and at the beginning of the nineteenth, several scientific men were attracted to this phenomenon. Albert Fortis (*Mémoires pour servir à l'Histoire naturelle et principalement à l'Oryctographie de l'Italie et des Pays adjacents*, 1802), Prof. Gerboin of Strasburg (*Recherches experimentales sur un nouveau Mode de l'Action électrique*, 1808), and Prof. Ritter, of Munich (see his report in the Tübingen *Morgenblatt für gebildete Stände*, No. 26, January 30th, 1807), were among the number, as well as the Abbé Charles Amoretti, librarian at Milan, to whom I have already alluded. As this mention of the pendulum is in the nature of a digression, although (as will appear) not without pertinence to my main argument, I content myself with an abstract from Ritter's article. He says:

"Take a cube of pyrites, native sulphur or any metal. Size and form are indifferent. We may use, for instance, a gold ring. This body is attached to a piece of thread, a quarter to half an ell long. This is held pinched between two fingers and suspended vertically, all mechanical movement being hindered. It is best to wet the thread slightly. In this condition, the pendulum is held over or close to a vessel full of water, or over any metal, as a piece of money or a plaque of zinc or copper. The pendulum insensibly assumes elliptical oscillations, which form themselves into a circle, becoming more and more regular. On the north pole of the magnet, the movement is from left to right; over the south pole, from right to left; over copper or silver, as in the former instance; over zinc or water, as in the latter. . . . Over an orange or an apple, on the side of the stem, the move is the same as over a south pole; on the opposite side, as over the north pole. The same difference in polarity is shown by the two ends of a fresh egg. It shows itself still more strikingly in the different parts of the human body, the head acting upon the pendulum like zinc; the sole of the foot, like copper; forehead and eyes, north pole; nose and mouth, south pole; chin, like the forehead; and so on, with all parts. The palm and the back of the hand act in opposite senses. The pendulum will move over every point of the finger, and even over the fourth or ring-finger, but, in that case, in an opposite direction. The finger has also the faculty of arresting or diverting the movement of the pendulum. It needs merely to be placed alone upon the table used in the experiment."

So much for the outline of Ritter's statement. He was at this time occupied with Campetti, above mentioned, and naturally he brought together in his thoughts the divining-rod of Campetti with the pendulum of Fortis (Fortis had experimented with it, and it was often called by his name, in consequence; but his death in 1803 deprived Ritter of his advice and aid in further tests).

Campetti was a young peasant from the borders of the *Lago di Garda*, who had seen the performances of Pennet, Dr. Thouvenel's last *protégé*, and had found himself possessed of similar powers. Not only Ritter, but Schelling and Franz Baader examined him. The opinion expressed by Ritter was, that the divining-rod is simply a double pendulum, requiring, to set it in motion, a force greater than those which move the pendulum. Ritter wrote this after consultation with Amoretti and others; and after either he or Amoretti had visited and consulted, at Padua, the great Volta.

But Professor Gerboin carried his scientific study of the pendulum to a much greater extent. His book contains in 356 octavo pages the records of two hundred and fifty-three experiments, and a most elaborate theory of "organo-electric force," in its different qualities, expansive, compressive, passive perturbatory, and active perturbatory. The simplest actions of these qualities may be indicated thus—to condense from the professor's somewhat verbose description:

By virtue of the *expansive* quality, which resides most abundantly in the thumb and fore-finger, a pendulum held between these two is caused to describe with its center of gravity a circle. The *compressive* quality, belonging characteristically to the middle finger, will not permit this motion, or will stop it—as when a highly *compressive* man touches the hand of an *expansive* man, which is holding the swinging pendulum. Contact ceasing, the movement recommences. The *passive perturbatory* is a high degree of the expansive, and the *active perturbatory* is in like manner a powerful *compressive*. The possessor of the former, if, while holding a pendulum he is suitably touched by one of the first or second class, will find the pendulum, if at rest, to start backward; and if in motion already, to reverse its motion. The fourth class is, like the second, negative in its action. Persons exercising either the compressive or the active perturbatory qual-

* Read at the Boston Meeting of the American Institute of Mining Engineers.

Digitized by Google

ity can not cause the pendulum to oscillate; they can only counteract or reverse its oscillations in the hands of others.

Considering that the author goes on to formulate the permutations and combinations of these qualities of force, their relations to the different fingers, and to a long list of organic and inorganic bodies, I may be excused from following further his intricate and obscure system. Elaborate as it is, the whole structure is absolutely baseless; and constitutes a capital example of what St. Paul denominated "science, falsely so-called." Its vast array of worthless experiments are merely so many ciphers in a row, with a decimal point instead of a unit at the head. When the distinguished chemist Michel Eugène Chevreul (long the chief of the Gobelin tapestry-works, and the author of a well-known book on Color, as well as other important works) took up the subject in 1812, he was not long in discovering that, when the eyes of the operator were blindfolded, so that neither his will nor his thought could consciously or unconsciously affect the movement of the pendulum, the data, arguments, and conclusions of Fortis, Amoretti, Ritter, and Gerboin, the organo-electric force, with its qualities *expansive*, *compressive*, and *perturbatory*; the south poles and north poles, the classification of the universe thereby; in short, the entire science, bag and baggage, disappeared!

Gerboin had pronounced the action of the divining-rod to be a case of *passive perturbatory*. Chevreul, as we shall see, put both the rod and the pendulum in a new category. But before proceeding to state his theory, I will devote a word or two to the evidence presented in our own country.

It is safe to say that most of it, like most of the evidence of the past, is open to the suspicion of at least an alloy of deception. Men who make money out of their reputed skill with the divining-rod and who could not make as much money or advertise themselves so widely if they claimed only a high degree of skill as prospectors, will almost inevitably ascribe to the rod what is due to other means of inquiry; will explain away failures, exaggerate successes, and not establish or execute or permit really thorough and sincere experiment. The most distinguished expert in this art on the Pacific coast has been repeatedly made ridiculous by the result of test experiments. On one occasion, as I learn from an eye-witness, who also reported the circumstances to the *Mining and Scientific Press* of San Francisco, this diviner was permitted to inspect a metallurgical laboratory, which always contained a large amount of gold, either in bullion or coin. After this inspection, he was brought (blindfold) again into the laboratory, and assured that no coin or bullion had been removed. Under these circumstances, he was requested to find the metal with his rod. The coin had all been put in its natural receptacle, the fire-proof safe; and the bullion had been fastened with wire to the under-side of a writing-table. The operator found neither of them, though the point of his rod was frequently within an inch of thousands of dollars. He probably suspected a trick, and he declared that the gold had been removed. When the bandage was again removed from his eyes, and the coin and bullion shown to him, he claimed that his rod had been diverted by the immense amount of treasure in a bank half a block distant! There have also been operators in California claiming to be natural magnets, and not using the rod; but they are not known to have accomplished any better success. One of these natural magnets was employed to trace a lost vein for a mining company at Grass Valley, the mine of which had been at one time the most productive in California. Under his direction, the company cut for many hundred feet, at an expense of from $30 to $40 per foot, through tough serpentine rock, and found nothing. Not only are these belts of serpentine at Grass Valley well known to be barren in general, but this particular belt was actually exposed in a cross-section, parallel to this expensive underground cross-cut, only one eighth of a mile away. The persons most familiar with the mining districts of the West declare that in Grass Valley, and elsewhere, the divining-rod has accomplished nothing of practical value. It is very recently announced by telegraph from Tombstone, Arizona, that a large body of ore has been found at a considerable depth, under a spot indicated by the "hooda-stick" (which, I suppose, is some sort of divining-rod) in the hands of a common workman. I need hardly say that such a discovery proves nothing. It would be of course presumptuous for me, in the absence of information as to persons and circumstances, to criticise this most recent case; but I can not forbear saying that nothing is more common in the experience of mining superintendents than the discovery of ore-bodies by workmen, who have carried for a long time the secret knowledge of their existence. Most frequently it occurs when a mine seems to to have been exhausted, or at least the superintendent does not know where to look for ore, and finally leases some portion of the ground to miners who, by a good luck that would be surprising if it were not so easily explained, go straightway into a bonanza. It is not always, however, the certain knowledge of the existence of an ore-body observed by workmen, and kept secret with a view to future profit, which guides these practical explorers. Often it is their great familiarity with the indications of the ground, and sometimes, let me add, the ignorance and pride of the manager himself co-operate with this result, by leading him to pursue some erroneous theory of exploration, and to refuse the advice of practical men. The so-called instinct of Mexican miners for finding ore, exhibited particularly in such irregular formations as those of the quicksilver mines of New Almaden, is, indeed, an unconscious practice of an unwritten science.

The scientific explanation of the movement of the divining-rod was given by M. Chevreul, in a letter to M. Ampère, published in 1833 in the *Revue des Deux Mondes*. This letter contained an account of the experiments made by the writer in 1812, more than twenty years before, with the pendulum. Finally, in 1853, M. Chevreul having been apointed by the Academy of Sciences upon a committee to examine a work on the divining-rod, wrote a report on the subject, including the "exploring pendulum" and the then novel wonders of "table-tipping."

This report was published in 1854 under the title *De la Baguette divinatoire, du Pendule dit Explorateur, et des Tables tournantes, au Point de Vue de l'Histoire, de la Critique et de la Méthode experimentale.* It is worthy of notice that this venerable *savant* is still active at the age of ninety-seven; only the other day, he spoke before the Academy, referring to a paper he had presented to that body, if I remember correctly, seventy years ago!

Chevreul ascribes the movement of the rod, apart from cases of deliberate deception, to minute, unconscious muscular movements; and these are caused, he thinks, by the imagination or intuitive or unconscious decision or expectation of the operator. An impression that the rod will dip at a certain point, or a wish that it would, or even, in some minds, a fear that it may do so, are all effective causes of the peculiar muscular movement. Stories describing motions of the rod so violent as to strip the bark from it, in spite of the resistance of the holder, do not disprove the above theory. The position of arms, hands, and fingers usually prescribed for the holding of the rod, as explained in the beginning of this essay, is one in which it is not easy (though not impossible) to produce by conscious effort the peculiar movement referred to. But it is also one in which skillful effort, if employed, may be easily disguised; and finally, it is one which invites muscular cramps, and produces muscular torsions and involuntary movements, not to be resisted successfully without a change of position. Under these circumstances, a man might easily twist the bark from a willow stick, and yet fancy he was trying not to do it.

In concluding this survey of the subject, I shall take a somewhat wider view than M. Chevreul, and my remarks, though based on his theory, should not be received as representing it.

From the mass of testimony, good, bad, and indifferent, the following propositions may be safely deduced:

1. The material, consecration, astrological relations, and ritual formalities of the rod are entirely irrelevant and indifferent to its efficacy. This disposes at a stroke of nine tenths of the science which the middle ages so laboriously accumulated on the subject.

2. The rod itself is entirely inert, unless in the hands of a human operator; and according to the declaration of the most famous experts, such as Aymar, Bleton, Amoretti, and many others, and a whole school of diviners who do not use the rod at all, it is merely an index, revealing and magnifying in visible results the peculiar inward sensations of the diviner.

3. The favorite and most convenient form of the rod (λ) is one which promotes involuntary movements and also permits deception.

4. The involuntary minute muscular movements may proceed either from the causes enumerated by Chevreul, or from a truly and purely physical sensation. To this I will presently recur.

5. The uses of the rod for discovering moral qualities, re-locating missing landmarks, tracing stolen property, prophesying the future, or even (as in the seventeenth century was the case) settling the orthodoxy of theological dogmas, will not now be seriously defended by any one. They belong to charlatanry and superstition.

6. The agency of demons we may also set aside, as a view outgrown if not disproved. The pious Jesuit Gaspard Schott (1662) who held this view, was, as we have seen, shaken in his faith, though not convinced, by testimony showing how often the rod failed to act, or gave unreliable indications. He half admits that, if Satan were at the bottom of it, it should work better. As an instrument of divination, it is unworthy of the devil! But, it might have been rejoined, that as a means of perplexing and misleading mankind, that distinguished expert could scarcely have improved upon it.

As old Albinus (*Das entlarvte Idol der Wünschelruthe*, 1700) quaintly says:

"Ich achte, dass kein verworrener Ding in der Welt zu finden, als das Wünschelruthen-Wesen, denn was Einem recht und tauglich ist, das ist vielen Anderen wieder unrecht und untauglich, dass aus solcher grossen confusion nicht viel Gutes zu präsumiren ist."

[I ween, that no confoundeder thing is to be found in the world than the divining-rod business; for whatsoever is right and fit according to one, the same is wrong and unfit according to others; until there is no good to be presumed, out of so great confusion.]

7. The application of the rod to the discovery of metals, coal, buried treasure, etc., is shown abundantly to be chimerical. The rules and methods, as well as the asserted performances, of its professors contradict each other; and innumerable failures and exposures have justly covered with ridicule their pretensions.

8. The transparent humbug of locating wells with the rod, to strike oil at depths of from a hundred to thousands of feet, needs no comment. In this case, there are positively no signs by which a given *spot* can be selected. The experience of neighbors may show a certain area to be probably productive; and within that area a certain line may be inferred, sometimes, to be the line of a productive channel. But if a keen observer, having gone so far, professes to select a point on that line, he is simply betting on his luck; and, as carried on in Pennsylvania, the bet is a safe one for the oil-smeller, who gets a handsome fee if he wins, and loses, in the opposite event, nothing but an hour or two of time.

9. The case is somewhat different with the discovery of springs, and (since ore-deposits always have been and often still are the channels of springs) of ore-deposits. Here we have much stronger and more abundant evidence in favor of the rod; and here, in my judgment, there is a residuum of scientific value, after making all necessary deductions for exaggeration, self-deception, and fraud. Keeping in mind that the rod is merely an index to the minute muscular movement, and that this movement may have a mental or a physical cause, let us consider (putting aside at once all cases of deliberate deception) the following facts:

There is undoubtedly a practical science of discovering mineral deposits and springs. The most skillful prospectors can scarcely explain how they decide upon the place where they dig; and yet, though they are by no means always successful, it is certain that they are more successful than the inexperienced. The books, from Agricola down, give rules and signs; but the practical explorer is unacquainted with the books. He has a science of his own, which affects his mind, without conscious reasoning, by the principles of association and memory. He recognizes in a new locality the tokens that he has become accustomed to associate elsewhere with a rich gulch, or an abundance of pay-quartz. Perhaps he never took conscious note of them; yet their recurrence affects his judgment. This practical skill is almost unerring within narrow limits. Under new conditions, it breaks down. Some of the most absurdly foolish gold-mining enterprises I have known have been set on foot by old California miners, who, returning to their former homes east of the mountains, have said at once of some ravine or hillside, that it was "just the place for gold." In like manner, certain

Digitized by Google

omens and signs from Cornwall have been carried around the world by Cornish miners. But whatever the errors of practical prospectors, the noteworthy point is, that in localities with which they are familiar (or in other localities where the conditions are the same), they come swiftly, surely, and without conscious reasoning to impressions and decisions. A decision of this kind would probably, in a man of suitable nervous organization, affect the muscles already constrained by holding a divining-rod, and the minute muscular movement or inward sensation might be unconscious.

The case is still plainer with regard to the discovery of springs. Every body knows that Indians in our desert West can find water where most white men can not; and the experienced frontiersman has learned the art from the savages. The conformation of the surface, the track of animals, above all, the presence or absence of certain plants, are his guides. In regions where the finding of water within a few feet of the surface is a question of life or death, it becomes a science very rapidly. The location of artesian wells is a different matter. Science will do that in a general way; but science will not determine a difference between one spot and another, ten or twenty feet away, the geological and topographical conditions being alike in both; and the selection of one of two such points as better than the other for a deep well is purely a piece of imagination or deceit. It must be remembered, however, that the diviner has in such a case an easy task. If possessed of sufficient practical judgment to decide that a certain area or line would probably be suitable for boring, he is pretty sure to be safe in selecting any point of it. But this, it will be seen, is very different from the unconscious skill which points out in the dry *arroyo* the very spot where water will be found in half an hour's digging.

In abundantly watered regions like New England, it is perfectly well-known that the springs follow, under or through the soil and above the bed-rock, more or less defined channels. A well may be dug at one point without success, and a subsequent attempt a few yards away may be successful. The superficial signs of these water-courses are often subtle, and they are little studied by the inhabitants in general. It is not necessary that a farmer, who will want to locate a well once in his lifetime, should know the signs of water, as a ranchman or *vaquero* must know them. Hence, men who are keen observers (in many instances, finding profit in the business) get impressions, amounting to a local science, of the "lay" of the rocks, the general courses of the springs, the differences in surface vegetation, the earlier or later greenness of grass, the presence of particular grasses and shrubs, the ascent of local vapors at sunrise, the behavior of frosts; in short, a hundred minute tokens which betray the presence, even at considerable depth, of a water-channel, and the point at which it comes nearest to the surface. The unconscious judgment of such an expert may decide upon a given spot over which he walks; and while he could undoubtedly come to this conclusion without having a rod in his hand, I am willing to admit seriously that the rod may help him make up his mind by emphasizing for him his own slightest tendency to a decision. It should be remembered here that even Bleton, the greatest of all the hydroscopists, generally used to go (if permitted) many times over a piece of land before finally locating a well, and often disregarded the first intimation of the rod. In other words, unless he felt sure, every time he crossed a given spot, that it was a good place to dig, he did not rely upon his first sensation or impression. Moreover, neither he nor any other hydroscope has ever accurately divined, except on an occasional lucky guess, either the distance from the surface or the quantity of a subterranean spring. Yet a very large spring, or one very near the surface, appears to have had, usually, a relatively greater influence upon hydroscopes.

This brings me to the final inquiry, whether there may not be, apart from unconscious skill or judgment, a purely physical effect produced by a subterranean spring upon a person walking over it. Electrical theories on this point were only possible in the days when the laws of electricity were little understood. We know now that the earth is a vast conductor, and that the tension of its currents is consequently so low as to be reckoned as the zero of the electricians' scale; hence, that no perceptible electrical current can leave a particular bit of the earth to pass through a human body and return. For this purpose, analogies between rock-contacts or fissure-veins and the voltaic pile are inapplicable.

But the effects of moisture and temperature upon the nerves are often striking; and here, I think, is a matter which writers on the divining-rod have generally overlooked. The distance at which animals will "scent water" is very great. Their faculty is supposed to consist in great sensitiveness to temperature and moisture. The quickness with which some people "catch cold" on the slightest exposure to dampness—particularly of the soles of the feet—is also a familiar phenomenon. Now, it is curious that among the most puzzling of the well-authenticated accounts of the divining-rod are related instances in which women, unacquainted with its use and not expecting it to work in their hands, have found it to dip, without their conscious help, over spots previously or subsequently shown to contain springs.

Here I would recall the remark of Amoretti, that the sensation of the diviner is one of heat or cold. These two are not easily distinguishable when minute and transient. What we call a chill includes both. Is it not probable that a single unconscious chill may be the physical result, to certain sensitive persons, of walking over a spring of water or a belt of rock or soil kept by running water cooler than the adjacent rock or soil, or a spot of surface made by the same cause damper than the surrounding surface? That these causes exist, is beyond doubt. Thermometrical measurements have not been made; but the way in which grass grows and snow lies and frost settles and vapors rise over springs, is due to the temperature and moisture of the ground in such places. Goethe in one of his novels (*Die Wahlverwandtschaften*, I believe), describes a lady as seized with a sudden chill upon a spot where subsequently the outcrop of a coal-bed is discovered. The incident is introduced without attempt at scientific explanation, and apparently to convey to the readers a vivid conception of the lady's extreme delicacy of temperament. I infer from it that such cases were known to the great philosopher, and that he believed such supersensitiveness to be in some way connected with the performances of diviners.

To this, then, the rod of Moses, of Jacob, of Mercury, of Circe, of Valentine, of Beausoleil, of Vallemont, of Aymar, of Bleton, of Pennet, of Campetti—even of Mr. Latimer—has come at last. In itself it is nothing. Its claims to virtues derived from Deity, from Satan, from affinities and sympathies, from corpuscular effluvia, from electrical currents, from passive perturbatory qualities of organo-electric force, are hopelessly collapsed and discarded. A whole library of learned rubbish about it, which remains to us, furnishes jargon for charlatans, marvelous tales for fools, and amusement for antiquarians; otherwise it is only fit to constitute part of Mr. Caxton's *History of Human Error*. And the sphere of the divining-rod has shrunk with its authority. In one department after another, it has been found useless. Even in the one application left to it with any show of reason, it is nothing unless held in skillful hands, and whoever has the skill may dispense with the rod. It belongs with "the magic pendulum" and "Planchette," among the toys of children. Or if it be worthy the attention of scientific students, it is the students of psychology and biology, not of geology and hydroscopy and the science of ore-deposits, who can profitably consider it. For us miners and prospectors, the advice holds good which was given us three hundred years ago by the wise Agricola, the father of our profession, who says the believers in the rod find some veins with it by accident. "*Sed idem multo sæpius perdunt operam, et ut venas invenire possint, nihilominus in fossis agendis defatigantur, quam adversæ partis metallici*"—"but the same people much more frequently lose their pains, and in order to discover veins have to fatigue themselves with digging, not less than the miners of the opposite school."

As a piece of sorcery, he goes on to say, the virtuous and respectable miner will avoid it; as a piece of science, it is inferior to the study of nature, following the indications of which, the skillful and prudent miner selects a good place for exploration, and "*ibi metallicus agit fossas*"—"there the miner digs"—to which business, rod or no rod, he is bound to come at last.

THE BRITISH ACCIDENT STATISTICS FOR 1882.

We are indebted to Mr. R. J. Frecheville, of Truro, one of her majesty's inspectors, for an early report on the production of the mines of Great Britain and of the accidents which occurred. Turning first to the mines classified under the Coal Mines Regulation Act, we have the following series of figures for the number of persons employed above and below ground, and the quantity of mineral raised, for the period from 1873 to 1882, both inclusive:

PERSONS EMPLOYED AND PRODUCTION OF ENGLISH COAL MINES.

YEAR.	PERSONS EMPLOYED.		Coal.	Total, including coal, fire-clay, iron-stone, shale, etc.
	Under ground.	Above ground.		
1873	407,808	106,341	128,680,131	143,041,246
1874	428,611	110,218	126,590,108	140,713,832
1875	427,017	108,828	133,306,485	147,700,313
1876	409,229	105,303	134,125,166	148,980,385
1877	395,025	99,366	134,179,968	148,846,260
1878	382,979	92,350	132,612,063	145,798,133
1879	385,179	91,631	133,720,393	145,306,369
1880	391,381	93,552	146,969,409	161,466,703
1881	399,387	96,090	154,184,300	168,959,931
1882	406,192	97,795	156,499,977	171,334,032

The general figures for the total number of accidents and deaths for the same period are given below:

ACCIDENT STATISTICS IN ENGLISH MINES.

YEAR.	Separate fatal accidents.	Lives lost by the accidents.	PERSONS EMPLOYED.		Death-rate from accidents per 1000 persons employed.	TOTAL OF MINERAL MINED.		Number of mines.
			Per fatal accident.	Per life lost.		Per fatal accident.	Per life lost.	
1873	973	1,069	528	481	2·079	146,867	133,677	3,938
1874	895	1,056	602	510	1·959	157,222	133,251	4,332
1875	927	1,244	578	430	2·321	159,331	118,730	4,501
1876	839	933	613	551	1·813	177,580	159,688	4,385
1877	864	1,208	572	409	2·443	172,276	123,217	4,231
1878	811	1,413	586	336	2·972	179,777	103,183	3,968
1879	782	973	610	490	2·040	185,890	149,400	3,956
1880	815	1,318	595	368	2·718	198,119	122,509	3,904
1881	844	954	587	519	1·925	200,189	177,106	3,847
1882	876	1,126	575	447	2·234	195,586	152,161	3,814

These data, it will be seen, are remarkably complete; and it is a source of much regret that as yet it has been impossible to show any thing like it for this country, even for a single year. We can not help believing that, when the Department of Industrial Statistics of the United States Geological Survey has once fully mastered the work it has so auspiciously begun, it will be able to turn its attention to the gathering of accident statistics. We know that the industrious chief of the department, Mr. Albert Williams, Jr., has already contemplated taking up this work, and we trust that it may not be long before he will be able to enter upon it systematically. The figures given above prove again the point upon which we have repeatedly insisted, that single years do not furnish a good criterion for judging of the number of fatal accidents and the deaths. The fluctuations are great, and it is not possible to trace from them any direct evidence of a decrease in the danger of the miner's work

The causes of the accidents and deaths for the past two years are fully

Digitized by Google

given in the following tables. For details over a series of years, we must refer to the data given in the issue of COAL of August 16th, 1882:

ACCIDENTS AND DEATHS IN ENGLISH COAL MINES.

	1882.		1881.	
	Fatal accidents.	Deaths.	Fatal accidents.	Deaths.
Explosions of fire-damp	35	250	31	116
Falls in mines:				
Falls of sides	127	129	114	114
Falls of roofs	332	339	325	336
Total falls	459	468	439	450
In shafts:				
Overwinding	3	3	5	5
Ropes and chains breaking	6	9	2	2
Ascending or descending by machinery	18	24	26	27
Falling into shaft from surface	6	6	5	5
Things falling from surface	7	8	6	6
Falling from part way down	23	26	30	30
Things falling from part way down	8	8	5	8
Miscellaneous	30	32	27	27
Total in shafts	101	116	106	110
Miscellaneous underground:				
Explosion of gunpowder, etc	11	11	17	17
Suffocation by gases	4	15	6	10
Irruptions of water	1	1	...	...
On inclined planes	54	55	43	45
By trams and tubs	99	98	83	86
By machinery underground	6	6	8	8
Sundries underground	22	22	24	24
Total miscellaneous underground	197	208	181	190
On surface:				
By machinery	9	9	18	18
Boiler bursting	2	2	1	2
Miscellaneous	73	73	68	68
Total on surface	84	84	87	88
Gross total	876	1,126	844	954

This shows a heavy increase in the mortality, due chiefly to the great number of lives lost in a few colliery explosions. A brief summary of the corresponding figures for the three preceding decades will aid in showing how the record of the last two years compares with that of the past:

RATIO OF PERSONS EMPLOYED TO EACH TOTAL ACCIDENT.

YEAR.	Explosions.	Roof and sides falling.	Shaft.	Miscellaneous underground.	Miscellaneous surface.	Total.
1851–60	3,000	681	1,339	2,453	5,257	318
1861–70	5,650	792	2,394	2,045	4,326	388
1871–80	11,372	1,104	3,991	2,747	5,529	559
1881	15,983	1,128	4,674	2,737	5,695	587
1882	14,399	1,098	4,989	2,558	5,999	575

RATIO OF PERSONS EMPLOYED TO EACH DEATH.

1851–60	1,008	653	1,161	2,074	4,872	215
1861–70	1,408	767	2,121	1,666	4,119	300
1871–80	1,795	1,069	3,557	2,535	5,369	425
1881	4,271	1,101	4,504	2,607	5,630	519
1882	2,015	1,076	4,344	2,423	5,990	447

TOTAL DEATHS.

1851–1882	7,760	13,356	5,205	5,402	2,350	34,073

In thirty-two years, 34,073 persons were killed in mining the coal and allied minerals in Great Britain, or at the rate of upward of one thousand people annually, one fifth of the deaths being due to the explosion of fire-damp.—*Coal.*

FURNACE, MILL, AND FACTORY.

Hendey & Meyer, of Denver, Colo., are running full-time, employing over one hundred hands. They are turning out at present two seven-foot hoisting-drums and two steel boilers of 70 horse-power each, for the Iron Silver Mining Company, Leadville; one double hoisting-engine of 100 horse-power, and an automatic cut-off steam-engine of the same capacity, to go with the hoisting-engine, for the American Smelting Company, Leadville, duplicating a former order. They recently made a 100 horse-power steam-engine for the Colorado Smelting Company, South Pueblo, and are now working on another machine of like capacity for the same company. They are also at work on a 70 horse-power steel boiler and an automatic cut-off engine of 60 horse-power, for a flouring-mill at Durango, Colo.; and have recently erected a 10-inch Cornish pump at the Evening Star mine, Leadville. They put in all the machinery at the Colorado Smelting-Works, South Pueblo, Colo., which expects to blow in before September first. Messrs. Hendey & Meyer erect every machine and give it a running trial before shipping.

The Foreign Exhibition Building at Boston has been recently supplied with a five-inch Curtis pressure regulator, in order to utilize the exhaust steam for heating purposes.

The Ashland Coal and Iron Company's machine-shops at Ashland, Ky., have just made and set up a new hydraulic press, christened Jumbo, weighing 6000 pounds, which will do duty principally in pressing wheels on or off axles, exerting a pressure of thirty tons and more if necessary. This company has contracted with Fairbanks, Morse & Co., for a tank and tower fifty feet high, the tank to hold 50,000 gallons of water, which will be held as a reservoir to draw water for the use of the works, and also as a protection and preventive in case of fire.

The foundry business of Mr. William Hamilton, Peterboro', Canada, is to be carried on by a limited liability company, known as the William Hamilton Manufacturing Company; capital, $200,000. The letters patent have issued to George A. Cox, William Hamilton, George Munro, Andrew Macfarlane, and Richard Hall, all of Peterboro'.

Iron and steel-works are to be erected at once at Gunnison, Colo., a company having been organized for that purpose with a capital of $5,000,000.

John Cover, superintendent of the Clare Furnace, New Castle, Pa., gives the following as the output of that furnace for one week's melting: 33⅓ cinder, 33⅓ lake ore, 33⅓ native ore.

1st day	101 tons.
2d day	106 "
3d day	105 "
4th day	107 "
5th day	110 "
6th day	116 "
7th day	110 "
Total	755 "

Size of furnace, 65 feet high; bosh, 16 feet.

The Philadelphia & Reading Coal and Iron Company will now manufacture rails sixty feet long, instead of thirty as before. The weight will also be increased about twenty pounds a yard. This step is taken on account of the increased weight of passenger cars.

The Phœnix Iron Company, at Phœnixville, Pa., has just built and put in operation one of the Taylor-Langdon patent gas ore-roasting furnaces. It is working very satisfactorily, giving a product of from forty to fifty tons per day of well-roasted ore. The Phœnix Iron Company will build several additional furnaces at Phœnixville.

Furnace No. 3 of the Phœnix Iron Company, at Phœnixville, Pa., of which Mr. Charles I. Rader is manager, produced, in the week ended August 16th, 478·26 gross tons of pig-iron on a fuel consumption of one ton and two cwt. per ton of iron. For the preceding week, the production was 442 tons. This furnace is sixty feet high and fourteen feet in diameter at the bosh, and uses a mixture of coke and anthracite for fuel.

An important contract has just been awarded to Messrs. Bellhouse, Dillon & Co., of Montreal, for the supply of the cast-iron water-pipes for the new Quebec Water-Works. The amount involved is between $250,000 and $300,000.

Three mills of the Acadia Powder Company, at Waverley, fifteen miles from Halifax, N. S., were blown to pieces on the 17th, by an explosion which was heard throughout a radius of seven miles. Three employés lost their lives and several others were hurt. The company has eight mills uninjured. The one next to those destroyed contained fifty tons of powder.

The appraisers of the property of the Manchester Iron and Steel Company, of Alleghany, Pa., Messrs. John W. Chalfant and David B. Oliver, have filed their report in Common Pleas No. 1. The assets are placed by the appraisers at $289,640.92. The rolling-mill and blast-furnace in Alleghany are estimated to be worth $425,000, subject, however, to a mortgage of $300,000. Henry Stauuton, for the assignees, filed a bond in the sum of $579,281.84 with George W. Cass, of New York, and J. M. Schoonmaker, Jesse H. Lippincot, J. N. O'Neill, and William N. O'Neill, of Alleghany County, as sureties.

Messrs. Sebastian Brown and Skipwith Wilmer, as counsel for William Keyser and John T. Mason, R., have filed a bill in the Circuit Court against Thomas H. Paul & Son and W. H. Whyte, trustee, asking for the appointment of a receiver and sale of the Paul Locomotive-Works, Baltimore. Mr. Whyte, as trustee, filed an answer consenting to the appointment of the receiver and to the sale of the works.

The Redstone Coal Company, it is said, will break ground within the next thirty days for a new rolling-mill on the Redstone branch of the Pennsylvania Railroad, either at Smock's station or at Hill's Bridge, one mile above.

The Colorado Coal and Iron Company has closed a contract with the Chicago Burlington & Quincy Railroad for the delivery to the latter of 5000 tons of steel rails.

H. K. Porter & Co., of Pittsburg, Pa., have under way another very small locomotive for hauling steel ingots at rail-mills. The cylinders are five inches in diameter by ten inches stroke, and the entire weight in working order, including water and fuel, is 6000 pounds. It has no cab, as it works inside of the mill; and no tender, as the water and fuel are carried on the foot-board. These locomotives are also used at sugar plantations for hauling cane on portable tracks, and are the smallest built in the United States for regular service.

The Edes, Mixter & Heald Zinc Company, of Plymouth, Mass., has recently opened valuable zinc mines in East Tennessee. The ore from these mines is found to be of very superior quality, being free from lead, arsenic, and other impurities. An analysis of the zinc made by Messrs. Ledoux & Ricketts, of New York, gave the following results: Iron, 0·017 per cent; zinc, 99·983 per cent. The spelter made by this company is soft and ductile and of unusual strength, making it especially desirable for such work as cartridge brass. The mines and furnaces of the company are near Knoxville, Tenn., the sales offices being at Plymouth, Mass.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

ATLANTA.—On this claim, the running of the tunnel at the east end continues with satisfactory results. As soon as the point settled upon has been reached, a large station is to be cut out and a main working-shaft sunk. This mode of working is caused by the configuration of Copper Mountain, in which this claim is situated.

CAVE.—The main shaft is now down forty-eight feet, in iron oxides and copper ore. The copper ore encountered consists of red oxide of copper and green carbonates, very similar to those met with in the 300-foot level of the Copper Queen. Another shaft, sunk 12 feet, is in red oxide of iron, and is situated 199 feet north from the natural cave.

HENDRICKS.—Work has been recommenced. The mine is the westerly extension of the Atlanta, and through both claims a ledge of lead carbonates is known to run, assaying in several instances from $60 to $95 per ton. Recently, some of the lead carbonate ore, carrying silver, from this mine, was reduced with the ore from the Tombstone camp.

TOMBSTONE DISTRICT.

The outlook presented by a visit to many of the properties which are at work, says the *Epitaph*, is encouraging in the extreme, and while there is nothing of startling importance to note, the steady work of the camp proceeds.

GILA COUNTY.

STONEWALL.—The mill is running night and day on tailings, with good results. The circulation of air in the drift on the 280-foot level is good.

GRAHAM COUNTY.

GREAT WESTERN CONSOLIDATED.—Three ingots of refined copper, aggregating fifty pounds, besides a small quantity of gold and silver, have been received in this city from Mr. L. B. Darling, of Providence, R. I. They are the result of a working test of 100 pounds of ore from the property of this company.

YAVAPAI COUNTY.

UNITED VERDE COPPER COMPANY.—Our notice of this enterprise last week was, without any intentional injustice, quite in error. We are now able to state from authority that the smelter was blown in at noon of August 1st, and up to noon of the 11th inst., or in ten days' uninterrupted run, the output of copper bullion was over seventy tons, or fully seven tons daily. The last weekly account was made up to August 11th, at which time shipments had been made of about thirty tons of copper, and teams were arriving to haul the remainder to Ash Fork on the Atlantic & Pacific road. The roads were not impassable, there has been no suspension, nor was there any deficiency of coke. The mountain road, built at great expense by this company, is said to be a remarka-

bly good piece of engineering. It is simple justice to the energetic superintendent, Mr. F. F. Thomas, to say that by his tireless efforts all the labor of opening the Verde property, erecting the furnace, building over ten miles of mountain road, introducing water in nearly a mile of pipe, etc., was accomplished in one hundred and four days from the day of his arrival (April 18th) on the property. The ores are carbonate and oxide, with enough iron to smelt them; and the slags run under one per cent from ores averaging over twenty per cent. The copper bullion is high grade, and portions of the ores carry a *ley* of the precious metals. The reserves of ore are said to be large and constantly increasing with the work of development.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

The Bodie *Free Press* gives the bullion shipments of the four operating companies of the district for the first half of 1883 as follows:

	Gold.	Silver.	Total.
Standard	$564,086	$79,107	$643,193
Bodie Consolidated	59,289	89,992	149,281
Syndicate	35,806	2,622	38,428
Bodie Tunnel			52,742
Total			$883,644

The Bodie Tunnel Company made only two shipments during June, the mill closing down before the end of the month. The shipments of the Standard mine during July amounted to $95,208.24. In the Syndicate statement, the shipment for July is included.

KENTUCK.—This Sweetwater property is turning out rich ore, and there is a great deal in sight. It is estimated that the bullion output will average at least $20,000 per month.

VIRGINIA CREEK HYDRAULIC COMPANY.—It is thought that the company has struck the old Mono channel, which proved so rich, having encountered a gravel bed running diagonally across the channel first started on.

PLACER COUNTY.

BLUE RIDGE.—This gold and silver mining claim with its extensions has been located. The ore is reported to run from $15 to $60 per ton; two shafts, one 17 and another 34 feet deep, have been sunk; also a tunnel run 193 feet to cross-cut the vein. The width of the vein is from 16 to 25 feet. It is about fourteen miles from Auburn. Wood and water are in abundance.

CANADA.

PROVINCE OF NEW BRUNSWICK.

A quantity of ore from the mines at Mineral Vale was recently shipped to Portland and Boston for treatment. This special shipment is made on account of newly discovered veins thought to be much richer than previous workings. It is expected that large quantities of this ore will be shipped to this country and England.

NOVA SCOTIA.

HALL-ANDERSON.—The work in mining and milling continues as heretofore.

OXFORD.—The superintendent reports every thing about the mine and mill in good condition. The late scarcity of miners, owing to the fishing season, seems now to be over, and he will now be able to open up all the different leads thoroughly. The ore in the mill lead continues of the same high grade. The face of the east bluff is now 25 feet high and shows enough ore for three months' work. He is sinking on the lake lead, and will let a contract for sinking the main shaft on mill lead as soon as he can get the tenders made. The mill is pronounced by mining visitors the finest in that country, or possibly in any country. The assay of tailings at the mine made from time show hardly more than a trace. A lot sent to this city this week, to be tested here, gave only 88 cents per ton. This from ore (though perfectly "free") is, to say the least, not a little remarkable when it is milling over $60 per ton.

RENFREW CONSOLIDATED.—At this mine, a sinking of 100 feet through barren rock has rewarded the management with a splendid strike, the ore looking fine and showing three feet in width.

COLORADO.

BOULDER COUNTY.

CELESTIAL.—A rumor states that this mine has been sold to English capitalists for $35,000.

CLEAR CREEK COUNTY.

PAY ROCK.—The mill is treating about 1000 tons of ore per month.

EAGLE COUNTY.

Considerable work is reported in the gulches tributary to Half Moon Gulch, in the southwestern corner of the county. Particularly is this true in Little and South Half Moon gulches. In the latter gulch are located the well-known Iron Duke and other mines. The Iron Duke is working under lease, and is shipping ore with considerable regularity. The ore is brought in on jacks; but as the ore ranges in value from one to two hundred dollars a ton, it readily bears this expensive method of transportation, and still leaves a fair profit.

GRAPHIC.—Included among the Little Half Moon properties is the group of claims controlled by this company, on which operations are to be resumed.

GILPIN COUNTY.

DELAWARE.—The lessees are drifting and backstoping at a depth of 300 feet. The ore contains considerable galena and nets from $6 to $50 per ton. The third quality is piling up, and will be sent to the concentration-works. The main shaft is 430 feet deep, but, owing to heavy flow of water, can not be worked to advantage below the 300-foot station.

EGYPTIAN.—Connection from the 400-foot west level with the 500-foot west level has been made through a winze. The body of ore at this point is continuous and of a fair average width. This affords the company quite an extensive body of stoping ground. The 700-foot east and west levels are showing up well, especially the west level, which is driven through a wide vein, the smelting ore being fully eighteen inches wide.

KING.—Development-work is confined to the sinking of the main shaft, now over 300 feet deep.

GUNNISON COUNTY.

A sale on a group of properties in the Elk Mountains is pending, which, if consummated, will cause $250,000 to change hands.

SYLVANITE.—Reports state that work will shortly be resumed. This property was discovered in the spring of 1879, and is noted for both the quality and quantity of ore it has already produced. But, like most other valuable properties, this has become involved in litigation and has been shut down for more than twelve months.

LAKE COUNTY.

The prospects are, that the California Gulch extension of the Rio Grande Railroad will not stop at Oro City, but make a turn at that point and run across portions of Breece and Iron hills, tapping all the leading mines on the latter hill.

The *Herald* states that a great deal of activity is at present displayed among the mining properties of Little Ellen Hill. Mere prospects, that have been permitted to lie idle for years past, are working again, and a number of claims have lately been added to the list of productive mines of the Leadville District. The ore secured from the Little Ellen Hill mines, in most instances, is only of medium grade; but as it usually occurs in large bodies, the expense of extraction reaches only a minimum of the average expense per ton of the mines of the district. In consequence, the profits are nearly if not quite as satisfactory as those resulting from the working of mines on Carbonate or Iron Hill. The ore generally is more siliceous than that of the mines in other portions of Lake County, and the expense of smelting a trifle heavier, but in return the mineral all contains an appreciable amount of gold.

ADLAIDE.—In pushing work on the ore-body recently opened in the vicinity of the Ward shaft, on the 160-foot level, the workmen ran into a streak of about fourteen inches of horn-silver. A test of a fair average piece of the ore made twenty-two and a half ounces of gold. Ores carrying chloride of silver in minute particles are frequently encountered in nearly all the mines of Iron Hill; but we believe this to be the first instance on record where large pieces of horn-silver ore were discovered in an Iron Hill mine.

AMERICAN SMELTER.—The new 110 horse-power engine, recently purchased, was set in motion recently. Another engine has been ordered, to take the place of the engine recently wrecked. Three of the large furnaces are in blast, and the fourth furnace, it is expected, will be started up. About twelve thousand tons of ore are on the company's premises.

ARKANSAS VALLEY WORKS.—These smelting-works have lately been provided with a new 125 horse-power Corliss engine. Five large furnaces are in blast at the works, and ore is reduced at the rate of about five thousand tons a month.

BREECE.—This iron mine is at work again, having recently received several large contracts for iron ore.

CHRYSOLITE.—Mr. Cuno, who is working a portion of the Chrysolite mine on a lease, is shipping from seventy to eighty tons of ore a day to Leadville smelters.

DUNKIN.—During the past five months, over one thousand feet of prospect-drifts were driven. The working expenses of the mine for July were about $1800, and the net earnings above all expenses $4500. No portion of the mine is now worked on the lease or tribute system. The company has now $22,000 in its treasury, exclusive of the earnings of this month.

IRON SILVER *vs.* A. W. GILL.—A suit has been instituted by the Iron Silver Mining Company against A. W. Gill and others, to recover $50,000, the alleged value of the ore extracted by the Smuggler lessees from the Iron Silver territory.

IRON SILVER.—The company is still engaged in making surface improvements, made necessary by the extension of its underground workings. At the Stone mine, a large new Worthington compound pump is being placed in position, having a capacity of 225 gallons a minute. A similar, but of smaller dimensions, is in use at the Moyer shaft, as well as two sinking-pumps. Two new winding-drums are also added to the plant at the Moyer shaft, and other improvements are in progress. On the Stone mine, where a number of hoisting and pumping-engines are employed, it has been decided to put in several large new boilers. The ground on this claim, owing to large stoping, has been sinking, and the old boilers are out of plumb. As new boilers will be required shortly, it was decided to put in a new battery, and place it in a secure position. The new boilers will possess at least one hundred and fifty horse-power, and are calculated to supply all the engines on the Stone mine with steam.

LITTLE ELLEN.—The concentrating mill attached to this mine, on Little Ellen Hill, belonging to the American Mining and Smelting Company, was burned August 16th. The mill cost about $100,000 originally, and was complete. It did not prove a success, and most of the machinery had been removed before the fire. It was insured for $20,000, and the insurance will probably cover the loss.

LITTLE PITTSBURG.—A lot of waste material placed in front of the Little Pittsburg office some four years ago, to fill a depression in the hillside and make a passable road, has been taken up within the past week, and replaced by surface soil. The material contained, according to the *Herald*, about thirty ounces in silver to the ton, and was shipped to the smelters. The work was done by tribute workers.

MOYAMENSING.—This lode, on Yankee Hill, has encountered a streak of ore, running high in silver. The material is a siliceous iron, carrying the silver in the form of chlorides.

WILLIAM WALLACE.—In the drift run at a depth of 528 feet, a twelve-inch streak of ore has been encountered, which shows a gray sand, slightly mixed with talc. The returns show from sixty-five to eighty-two ounces in silver to the ton, and from forty to sixty per cent of lead. The mineral bears a greater resemblance to the high-grade lead ores of the Carbonate mine than to the ores of the Big Chief and Clontarf. The owners have expended a large sum of money in prospecting this property for the last three or four years. The above is the first ore that has been found.

PARK COUNTY.

EVERLASTING.—This comparatively new property, situated on Mount Bross, is opening out into quite a bonanza. The mine shows a three-foot contact-vein of ore, from which fifteen tons have been shipped, averaging $209 to the ton.

KANSAS.—Work has been started again.

SOVEREIGN.—Regular ore-shipments are made to the Pioneer stamp-mill. The product of the mines is free-milling gold rock. Air-compressors, machine drills, and other approved appliances are used to facilitate work.

PITKIN COUNTY.

The parties who recently purchased the Aspen smelter have opened a bank in that town, and made other preparations for business. The smelter is enlarging, and the purchase of ores is in progress.

SAN JUAN COUNTY.

MINERAL CREEK CONCENTRATING COMPANY.—The superintendent writes that arrangements have been completed for the erection of a thirty-ton concentrating plant at the town of Chattanooga, Red Mountain Mining District. Contracts have been let and work will be prosecuted without delay, it being the intention to push the work so as to have the mill in running order by the first week in October.

PULASKI & WATERFALL.—Reports state that New York parties have purchased these mines, in Bridal Vein Basin, for $65,000. Several adjoining properties have been bonded by these same parties.

SUMMIT COUNTY.

Concentrating devices are being put in a number of the mines and metallurgical works of this county. The Keystone Bullion Company is putting in six Metcalf concentrators. A new concentrator of forty tons capacity a day is erecting at Governor, and rigs are at work at the Lincoln. The Elyria smelting-works have been leased by Messrs. Newcomb & Musgrove, who are engaged in placing concentrating machinery in the building. The mill is to be used in treating Gibson Hill ore, and also in doing general custom-work.

DONCASTER CONCENTRATING-WORKS.—It is stated that Leadville parties contemplate the purchase of these concentrating-works at Kokomo, and enlarging the establishment to fifty a day capacity.

PAYMASTER.—This property consists of the Paymaster, Silver Ball, and Seven Thirty lodes, or 4500 feet on a large vein of argentiferous galena, 6 feet in width. They are only down 75 feet, but produce from 30 to 50 tons of ore per day. Assays run from 10 to 160 ounces per ton. The plant erected to work the mines and ore consists of a concentrating-mill, in which is a 50 horse-power engine and boiler, Blake crusher, Cornish rolls, Hartz jigs, and Rittinger tables, designed to treat 40 tons of ore per day.

ROBINSON CONSOLIDATED.—The president, it is reported, has stated to the New York *Evening Stock Report*, on his return to the city that the mine never looked better since he was connected with it. Mr. Greer owes to the company a small amount of royalty, which is secured to the company. The company only owes $3100, and has on hand $17,000 cash assets. The reports about the company's having $10,000 debt and about being responsible for any claims besides the above $3100 are not true.

Digitized by Google

DAKOTA.

CALEDONIA.—The superintendent reports for the week ended August 12th: Ore produced—from 300-foot level, 896 tons; 400-foot level, 154 tons. The 460-foot level header advanced five feet, making a total of twenty-five feet. There is no change to report in the appearance of the mine. The mill is running to its full capacity.

FATHER DE SMET.—The report for the week ended August 7th shows: Ore extracted from first level, 750 tons; second level, 750 tons; third level, 525 tons. Ore milled, 2025 tons. Golden Gate cross-cut, third level, advanced six feet; total, twenty-five feet. Work stopped. Golden Gate south header advanced seven feet.

GEORGIA.

The scarcity of water continues, and the consequence is, that but little work is done at the various mines in Lumpkin County.

IDAHO.

FISH CREEK COPPER MINES.—Arrangements are making to have a copper matting furnace constructed on Little Wood River, to operate upon the rich silver and copper ores of that section. The furnace is of the Rankin & Brayton make, and will run 20 tons of copper matte daily, of an average value of $160 per ton. The plant is expected to be in operation soon, and money will be on hand to purchase ores.

MAYFLOWER.—The vein is reported to be sixty feet wide at the end of the lower tunnel, 900 feet in from the mouth. Burleigh drills will be used to chamber out the ore and expedite the development of the mine. The Mayflower mine has twice the actual amount of pay-ore now in sight that was shown up at the time the mine was purchased, the price being $375,000.

PHILADELPHIA SMELTING COMPANY.—Work has begun on the Silver Star mine, the property of this company. The ore-body is strong, regular, and high-grade. The chances are very favorable for early shipments of ore from the mine to the smelter.

SILVER FORTUNE.—The mine has been bonded for $30,000. A shaft sunk 30 feet on the vein struck water, but exposed a solid body of high-grade galena ore, three feet wide. The bondholders are now developing it.

MAINE.

It is reported that the West Luber silver mines, in Washington County, are to be worked again, and that a new mill is to be erected.

MOUNT MICA.—Operations have been resumed on this property.

STEWART.—Developments at this copper mine are progressing favorably. Two drifts and a cross-cut are in progress from the bottom of No. 3 shaft, and an open cut at another point on the property is extending. All the openings are showing well.

MICHIGAN.

A new company, composed of prominent men in Marquette and Houghton counties, will be organized in Ishpeming shortly, to prosecute work on a quartz belt in the vicinity of the Ropes mine, which has been proved to carry well in gold and silver.

CALUMET & HECLA.—The old board of directors have been re-elected. Mr. Agassiz was re-elected president, and C. W. Seabury secretary and treasurer. The financial statement given out for publication shows that the surplus April 30th, 1883, was $1,980,824.53, dividends to the amount of $2,000,000 ($20 per share) having been paid during the year. The above surplus is about $1,400,000 less than on April 30th, 1882, the reduction having been caused in part by the drop in copper and by the expenditure of $1,250,000 for land.

CLEVELAND IRON MINING COMPANY.—At the meeting of stockholders, to be held in Cleveland, September 5th, a resolution will be offered authorizing the board of directors to sell and convey all the lands and real estate of the company in the city of Marquette, Marquette County, together with all its rights, privileges, and reservations in streets and other property appurtenant thereto, and all buildings, improvements, docks, tracks, water and riparian rights owned by it or in which it has any interest.

DETROIT.—Sinking is in active progress in the new shaft, which will, when completed, be the main hoisting-shaft. It is now down 108 feet in blue slate, somewhat mixed with jasper, and will be sunk 14 feet more, when drifting will be commenced eastward toward the present workings. The mine is now getting out about 120 tons of ore per day and is steadily shipping to Detroit by way of the Detroit, Mackinac & Marquette Railrord. Some exploring has been going on in the south part of this property, below the bluff of diorite; but this has been abandoned for the time being.

ROPES.—The stamp-mill was put in operation August 14th. The entire plant worked without a hitch of any kind. The Ishpeming *Agitator* says: Of course, nothing has as yet been learned of the milling qualities of the rock, nor will it be given out until a run of several weeks has been made.

MONTANA.

The Queen of the Hills and the Homestake mines, in Montana District, have been bonded for six months to I. G. Baker, of Fort Benton, for $60,000. Mr. Baker will organize a company to develop the mines and reduce their ores. These leads are already well developed.

LEWIS & CLARKE COUNTY.

The mining industry in the vicinity of Helena is having, according to the *Independent*, its boom, though not yet in any extravagant manner. The effect of the liberal policy inaugurated by the railroad magnates has been to stimulate development to such an extent as to render many properties—heretofore idle and considered of little value—quite promising, and the well-known paying mines are adding to their facilities, in some cases very extensively.

BOSTON & MONTANA.—A contract has been made with the Union Iron-Works to put in 24 pans and 12 settlers, besides 48 settling-tanks, at the sixty-stamp mill of the Gloster mine. Another boiler will be added, making four that will be used to furnish power, and a 200 horse-power engine will be added to the present plant, to run the new machinery, which will make an aggregate of 300 horse-power in the mill when completed. A new building, 60 by 190 feet, to accommodate this machinery, will be erected immediately, and the whole will be in working order within ninety days. At the Gloster, another contract will be let to sink the shaft 100 feet deeper for the fourth level, and at the same time start two winzes, one on each side of the shaft, and about 75 feet distant, so as to be able at once to run connecting levels and have plenty of ventilation as well as new ground opened for stoping.

GREGORY CONSOLIDATED.—The old concentrator is to be torn down and a new one erected having a capacity of 75 tons per day. It will be equipped with two of the largest crushers and four of the largest rolls made, and will have two compartments. The Ætna Iron Foundry, of San Francisco, has contracted to complete the concentrator and have it in running order within three months from date. At the mine, for a distance of 400 feet along the sixth, which is the lowest level, the galena is continuous, the ore-product very regular in value, and nearly all that is taken out carries sufficient silver to pay.

NEVADA.

The total amount of ore extracted in Eureka County for the three months ended June 30th amounted to 18,990 tons, according to the returns made by Assessor Wallace.

BAY STATE.—Ore has been shipped to the Eureka Consolidated furnaces. The mine is looking well. About eight tons per day are now shipped that work from $52 to $70 per ton. In addition to this, about 35 tons are shipped per month that will average $200 per ton.

ONONDAGA.—About 80 tons a week are shipped to Salt Lake. The bottom of the shaft, 110 feet from the surface, shows a body of ore five feet wide that assays high.

RUBY HILL.—The tunnel is in nearly 400 feet. The face is in very favorable-looking broken limestone. Prospecting will be carried on in this mine until ore is struck.

SILVER CONNOR.—A shipment of low-grade ore was recently made that assayed nearly $60 a ton.

COMSTOCK LODE.

The Cornish pump at the Combination shaft is fast lowering the water, which was up over the 2600 level, pending repairs to the broken rod and bob-pin. During the absence of Superintendent Patton, nothing has been done at the face of the north drift of the 3000 level in the Union. Two thirds of the face are still in ore. Sinking the joint winze is making good progress.

GOULD & CURRY.—Good headway is making in the new east drift on the 2500 level. It starts from the southwest drift, which was run out to the Savage line, at a point about 200 feet south of the shaft, and is now out about 100 feet. The face is in dry vein porphyry. There is, indeed, no water in any of the drifts on the 2500 level of the Gould & Curry; but north, in the Best & Belcher, the ground is very wet. The water in the Curry appears to lie out near the west wall. The new east drift will really have the effect of a cross-cut. Its course is east, 20 degrees south.

HALE & NORCROSS.—Pending repairs of the Cornish pump at the Chollar-Norcross-Savage shaft, the water rose above the 2000 level; but the pump is going on now as usual. The temperature on the 2600 level is now but 98 degrees, and it will doubtless go still lower when the water has been lowered to the old mark in the shaft.

UNION CONSOLIDATED.—No work has been done in the face of the north drift on the 3000 level recently. Meantime, the main west cross-drift has been timbered up at the point from which starts the north drift, and work has been pushed as usual in the joint Sierra Nevada winze below the 3000 level. As it now stands, about two thirds of the face of the north drift are in ore. As soon as the superintendent returns, work will doubtless be resumed in the face, and the drift pushed on the north to the Sierra Nevada line.

NEW MEXICO.

BILLINGS SMELTER.—The smelting-works, situated at Socorro, are now almost completed and will blow in shortly. There are more than a thousand tons of ore in the bins. There will be two furnaces, each with sixty tons capacity.

KINGSTON CONCENTRATION-WORKS.—The capacity of the works is small as yet, the present plant of machinery being erected as an experiment to demonstrate the feasibility of concentrating the low-grade ores of the vicinity of Kingston. The result of a run made upon bullion ore, average value $30 per ton, is given as follows: concentrates, as nine to one; value, $243, showing a loss of only ten per cent. The ore in this instance was difficult to treat.

NEW MEXICO & ILLINOIS.—The Eureka smelter, the property of this company, has closed down after a successful run of over a week. It was the first trial of the machinery, and it gives complete satisfaction. There is scarcity of iron ore for fluxing, and as soon as a supply is obtained, the smelter will start up and run permanently. It is expected that the other smelter will start up shortly. Iron ore of good quality and quantity has been found, and it is thought no further delays will be occasioned by the lack of that article for fluxing. The coke is supplied from Trinidad, and is taken in wagons from Bernalillo to Copper City at a great expense.

UTAH.

BOX ELDER COUNTY.

LAST CHANCE.—The Salt Lake *Tribune* says that when Mr. Cullins left this mine, years ago, it had about a foot and a half of ore, upon which they had run 65 feet, which was 20 per cent lead, 30 per cent sulphur, and carried 50 ounces in silver and a little gold. The sulphur was easily burned out by spreading the ores on cord-wood and setting fire to it. Afterward, there were quarreling and mismanagement and waste, and, of course, in time, complete abandonment. At present, Messrs. Bambergers have it. They are running a long, deep tunnel. It will, it is supposed, also furnish a live stream of water to reinforce the limited supply in Can Fork.

SILVER MOUNTAIN.—Good progress is made. About eighty tons of ore are on the dump, which averages about seventy-five ounces silver and forty-five per cent lead. A road is building to the mine, which will soon be completed, and then ore will be sent to the smelters.

PIUTE COUNTY.

BULLION CAÑON.—This company's ten-stamp mill at Marysvale was recently started on a test run of second-class Pluto ore. The assay of this ore gave about 34 ounces silver per ton, and was found easy to work. The capacity of the mill is from twenty-four to thirty tons per day. After making the tests, the mill was shut down for the purpose of putting in a Frue vanner. It will be started again as soon as this has been done. The property is now in the hands of the same men owning and managing the Pluto property. The first bar of bullion, weighing 515 ounces, was shipped to Salt Lake City. An assay showed it to be 927 fine in silver, and 18 fine in gold, the value of the bar being over $700.

SEVIER COUNTY.

The discovery of a ledge of copper ore is reported. A tunnel of about 35 feet has been run in to cross-cut it. The ore seems to consist of ruby, black, and red oxides, and ranges in assays from 15 to 45 per cent copper, with a perceptible amount of gold. A new district has been formed and is to be known as the Henry District, and the mine is located as the D. A. Giles copper mine. As usual, this deposit is stated to be an "immense and wonderful body of copper ore," and the immediate attention of capitalists is asked by the local papers.

SUMMIT COUNTY.

CRESCENT.—Shipments are regularly made. The ore is sampled at Mackintosh's Mill. About 1200 tons of ore are piled on the floor and in the bins, and the place is crowded with daily receipts.

WASHINGTON COUNTY.

This county is fortunate enough to have within its limits ore which runs as high as $130 in silver—so it is stated. A shaft 87 feet at an angle of 60 degrees has been sunk in this. At this depth the vein has pinched out to a mere line. A drift 20 feet deep has been run horizontally into the hanging-rock. This ends in the vicinity of a cave, exhibiting a high grade of carbonate ore.

SILVER REEF.

STORMONT.—The official report of August 13th is as follows: Our best stope now is in 23 winze ground, and the following are assays from a point about halfway between the 4th and 5th levels, where the stope is going down a moderate dip underhanded, and all solid ground below except as cut by the 5th level: 14 inches, $13.76 per ton; 14 inches, $35.14 per ton; 12 inches, $157.69 per ton; 12 inches, $7.17 per ton; 6 inches, $73.16 per ton; 18 inches, $36.08 per ton. A splendid stope of ore, and will go down, I hope, a good distance yet.

WYOMING.

SILVER CROWN DISTRICT.

COPPER KING.—At this mine, the principal one in the district, two shifts a day are at work, and a depth of sixty-five feet has been attained. They will soon begin two drifts, to test the width of the vein. New machinery will shortly be on hand, to facilitate the hoisting of ore. While the ore is varied in appearance and value, it all shows native copper in considerable quantities.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Aug. 24.

The mining market this week has been principally confined to four stocks, namely, Robinson, Sonora, Barcelona, and Alta-Montana. Robinson has suffered a sharp decline and closed weak to-day. Sonora has about held its own and has been steady. Barcelona sold a little weak to-day, and Alta-Montana has been steady throughout. Outside of these stocks, the dealings have been limited, and prices, generally, steady. A full summary of the market is given below. The total number of sales aggregates 142,010 shares, as against 137,900 last week.

The Comstock shares have been quiet and steady. California sold from 35@40c. with a small business. Consolidated Virginia was quiet and strong, selling from 57@66c. Sierra Nevada had a small business at irregular prices; it sold from $4@$4.20@$4.10. Mexican was quiet and steady at $3.35@$3.75. Ophir sold at $3. Consolidated Imperial records a small sale at 5c. Gould & Curry sold at $2.85. Savage sold, assessment unpaid, at $1.80. Best & Belcher, with one small transaction, sold at $3.90. Sutro Tunnel was moderately dealt in and was irregular; it sold at 19@21@20c.

The Leadville stocks were also quiet and steady. Amie sold at 15@14c., with moderate transactions. Chrysolite was quiet and a little weak, selling from $1.10@$1. Dunkin sold at 23c., with a small business. Breece developed a little strength, selling from 18@23c., with a business of 2600 shares. Iron Silver had a small business at strong prices; it sold at $3@$3.20. Little Chief was quiet and strong, selling from 35@45c. Little Pittsburg records a small business at weak prices; it sold from 70@60c. Climax was quiet and steady at 9@10c.

The Bodie stocks were very quiet and were steady. Bodie Consolidated was quiet and weak at 25c. Standard had a small business at steady prices, selling from $5.50@$6. Bulwer records a transaction of 100 shares at 70c.

The Tuscarora stocks were almost neglected and were weak. Argenta sold at 20c. Navajo was quiet and weak at $2.90. Elko Consolidated records small transactions at weak prices, selling from 15 10c.

In the miscellaneous list, Alice has been quiet and weak, selling from $2.40@$2. Bassick sold from $9.75@$9.50, with small transactions. Hall-Anderson was moderately dealt in at steady prices; it sold from $1@$1.05. Homestake was quiet and steady at $17.75@$17.63. Horn-Silver had a fair business at strong prices, selling from $6.25@$6.75. Northern Belle was quiet and steady, selling from $6.75@$6.50. Robinson has been very active and very weak; it sold from 64@49@51c., the business aggregating 39,700 shares. Sierra Grande was quiet and steady, selling from $1.15@$1.05. Stormont records a transaction of 500 shares at 20c.

Alta-Montana has been very active at steady prices, selling from 6@5c. Barcelona records a large business and was weak, selling from 39@34c. Caledonia sold at 62c. Central Arizona was moderately dealt in at steady prices, selling from 15@20c. Decatur records a very small business at 2c. Eastern Oregon has been fairly dealt in and has been strong; it sold from 92@98@96c. Rappahannock sold at 6c., and Red Elephant at 6c. The business in both stocks was small. Sonora Consolidated has been actively dealt in at steady prices; it sold from 24@26c.

The Tip Top Silver Mining Company, of Arizona, has levied an assessment of twenty-five cents a share, delinquent September 24th.

MEETINGS.

Baldwin Mining and Milling Company, No. 115 Worth street, New York City. Annual meeting of stockholders and election of trustees, September 11th, between three and four o'clock P.M.

Esmeralda Mining Company, No. 35 Broadway, Room 69, New York City. Annual meeting of stockholders and election of trustees, September 1st, from twelve M. until one o'clock P.M.

DIVIDENDS.

The Oxford Mining Company, of Nova Scotia, announces its regular monthly dividend (No. 6) of five per cent, payable August 25th.

The Smuggler Consolidated Mining Company, of Colorado, has declared a dividend of twenty-five cents per share, or $15,000.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway; report as follows for the week:

Friday of last week witnessed an upward movement in petroleum to $1.11⅝, though the news from the wells was bearish, and it appeared to be due principally to manipulation. The fluctuations through the week have not been very great, $1.11⅝ being the highest, and $1.07½ the lowest.

Porcupine well No. 9 has been a large producer, and being on the outer northern edge of Balltown, it is regarded as important in showing the possibilities of a farther extension of the fertile territory to the northeast, in which direction several important test-wells are now drilling. The result of this development-work ought to exercise an important influence on the future course of prices; but it will probably be two or three weeks before any thing conclusive will be known about these new undertakings.

One of the surprises of the week was the sharp advance in refined oil to 8c. on last Saturday, and an equally sharp decline Monday morning to 7⅝c. The Standard Oil Company has the control of the prices of refined oil. Rumors have been in circulation for some days about a consolidation of the Standard and tidewater companies, but the report is denied.

No great fluctuations are likely to occur during the coming week, and those who buy on a break of two or three cents, or sell on a sudden spurt, will have the best prospect for a profitable return.

The following dispatch from Titusville, Pa., has been received: The United Pipe Line Company has issued a circular to the oil exchanges of the country, proposing that they appoint gaugers to accompany the United Pipe Line gaugers on their annual inspection, in order to verify the figures given to the oil trade by the company, and to inspect its books. The net stocks held by the United Pipe Lines, according to the statement made on August 10th, were 33,995,765 barrels. The gauging of all oil-tanks will be accomplished on September 1st, and the oil exchanges will appoint ninety-one gaugers, sixteen inspectors, and a number of clerks to accompany the United Pipe Line officials. The gauge given to the trade to-day of the production of Forest County shows that the Cooper tract, with 103 wells, is yielding 3290 barrels, and Balltown, with thirty-six wells, 4790 barrels. Porcupine No. 9 is now flowing at the rate of twenty barrels an hour.

he following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Aug. 18.....	$1.10⅝	$1.11	$1.09⅝	$1.10	2,056,000

Total sales.					13,344,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, Aug. 23.

The market for mining stocks, if the limited transactions of the past week at the regular brokers' board can be called a market, has lapsed into a state of chronic dullness, from which it will require a mighty effort to lift it. At the Boston Mining Exchange, there has been the usual trading in the two or three specialties dealt in; but there is no feature worthy of mention; in fact, a summer dullness pervades the whole atmosphere, and we can not look for much improvement, either in the volume of sales or in prices, until later in the season. In copper stocks, Calumet & Hecla sold in the early dealings at $245, but there being no orders to buy, a small lot was pressed for sale yesterday, and $241 was the result. To-day it sold at $240, and more offered at that price, with $235 as the best bid. Quincy steady at $45@$45½; but few sales were made, and the stock is not offered at less than $45½. Atlantic sold same as last week, at $10. Franklin, a small lot sold at $9½, but it is freely offered at $10, and no bids for round lots. Pewabic, firm at $3, which is bid, and none offered. The reports from this mine, as well as the Huron, continue of a favorable character. The rest of the list was neglected, and with no disposition to operate in any of the low-priced stocks.

In silver stocks, there is virtually nothing doing at the Board. Two hundred shares Catalpa at 40c., 200 Harshaw at 50c., 300 Sullivan at 87½c., and 1800 San Pedro at 25@17c. comprise all the recorded transactions for the week. At the Mining Exchange, Bowman Silver Company, at 16@18c.; Massachusetts & New Mexico, at 4@5c.; Catalpa, at 37½c., and Sullivan, at 80@92½c., are the principal stocks dealt in.

3 P.M.—There was no improvement in the market this afternoon. Closing prices: Calumet & Hecla, $245 asked. Allouez, $1¼ bid. Bonanza, $1½@$1¾. Franklin, $9½@$10. Osceola, $17 bid. Pewabic, $3 bid, $3½ asked. Quincy, $45 bid. Silver Islet, $3 bid. Sullivan, $⅛@$1. Bowman, 17c. bid. Massachusetts & New Mexico, 4@5c.

BULLION MARKET.

NEW YORK, Friday Evening, Aug. 24.

There is nothing new to note of the silver market. It continues tolerably firm abroad, but with sterling exchange weak and declining here.

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Aug. 18	50⅛@50⅝	110⅛	Aug. 22	50⅝	110¼

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended August 24th, as compiled from various sources, amounted to $214,000, as against $210,000, reported for the previous week. The receipts from January 1st, 1883, to date are $7,391,974.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended August 18th	$195,000
Corresponding week last year	298,435
Since January 1st, 1883	8,331,524
Corresponding period last year	42,748,698

Imports.

Week ended August 18th	$370,168
Corresponding week last year	108,161
Since January 1st, 1883	8,221,833
Corresponding period last year	2,369,962

Foreign Bank Statements.—The governors of the Bank of England have made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £243,000 bullion, and the proportion of its reserve to its liabilities was raised from 46 9-16 to 49 11-16 per cent, against 38⅝ per cent at this date a year ago. August 23d, the bank made a further gain of £59,000 bullion on balances. The weekly statement of the Bank of France shows a loss of 1,275,000 francs in gold and a gain of 1,900,000 francs in silver.

Digitized by Google

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

METALS.

NEW YORK, Friday Evening, Aug. 24.

Copper.—There is not much change in the situation. Current demand and offerings are very moderate, and there is as yet no movement looking toward prices for the next contract sales, which are due some time next month, unless negotiations are protracted. England is unchanged.

The *American Architect* has the following on copper roofing, which is of great importance to the trade: The *Scientific American* mentions the decline in the price of copper as likely to lead to the increased use of that metal in building. At present, the material for a copper roof costs, at the outset, only about twice as much as tin, and as the latter must be repaired and painted about once in three years, and in fifteen or twenty years must be renewed altogether, the copper, which never needs painting, and is practically indestructible, is much the cheaper material in the end. There are in Boston many copper roofs, put on about forty years ago, which show no signs of deterioration; and the metal is still much employed in that city for cornices, gutters, and rain-water pipes, as well as for covering bay-windows, and in many other ways, in place of galvanized iron, which is much inferior in beauty and durability, and not very much cheaper. The copper has the additional advantage of needing no paint, so that the delicate lines o artistic work are in no danger of being filled up, and the metal increases rather than diminishes in beauty, by the slow formation of a bluish-green patina over it. For flashings, as well as other portions of roof-work, copper is much superior to zinc or tin, and with the aid of a certain amount of lead, the most difficult problems in roofing can be successfully and permanently solved.

The following are the British Board of Trade returns for the first seven months of the year:

	—Jan. 1 to July 31.— 1883. Tons.	1882. Tons.	1881. Tons.
Imports:			
Pure in pyrites	9,853	9,871	8,170
" precipitate	12,253	10,385	11,685
" ore	8,312	8,361	8,472
" regulus	5,770	4,779	3,053
Bars, cakes, etc.	20,247	16,088	18,335
	56,435	52,484	49,715
Exports:			
Raw (English)	9,736	6,870	10,989
Sheets	9,279	8,677	7,686
Yellow metal at 60 per cent.	6,646	6,475	5,192
Brass at 70 per cent	1,950	1,835	1,813
	27,611	23,857	25,680
Foreign	7,203	6,875	7,463
	34,814	30,732	33,143

Tin.—Sales during the week aggregate about 200 tons at 21@21⅛c. spot, which we quote for long lines while jobbing lots, 30 days, bring 21⅜c. London cables £93 15s. @£94.

Lead.—The deadlock in this metal continues. Offerings are light, though stocks are known to be heavy, a fact which encourages consumers in the belief that lower prices may be looked forward to. Common has been selling in jobbing lots at 4·20@4·25c.

Messrs John Wahl & Co., of St. Louis, wire us as follows to-day:

Our market is dull and quiet, and prices are unchanged. We quote: Refined lead, 4c.; and Common, 3·92½@3·95c.

Messrs. Everett & Post, of Chicago, send us the following dispatch:

In consequence of a considerable increase in the inquiry for both common and refined lead, a little more is asked by sellers. Business has, however, been only moderate in amount, transactions for the week footing up to 700 tons of common and refined. Our market is nominally 4·05@4·07½c.

Spelter.—Very little is doing. We quote 4⅝@4⅝c. nominally for good ordinary Western.

Antimony.—This metal is quiet, quotations remaining 10¼c. for Cookson's and 9¼c. for Hallett's, for jobbing lots.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Aug. 24.

The following are the quantities of iron and steel sent from Great Britain to this country for the first seven months of this year, ended July 31st:

	1881. Tons.	1882. Tons.	1883. Tons.
Pig-iron	217,641	274,171	168,801
Old iron for remanufacture	50,589	59,665	36,143
Steel unwrought	63,095	104,349	23,641
Tin plates	96,871	127,962	120,620
Hoops and sheets	16,724	18,816	19,153
Bar, angle, bolt, and rod	7,421	13,276	6,398
Railroad iron and steel	186,491	142,023	40,144

American Pig.—Business has been restricted to small lots, buyers pursuing strictly a hand-to-mouth policy. We hear of the sale of a lot of from 800 to 1000 tons, but are unable to learn the particulars. No. 1 Foundry continues firm at $21.50@$23 for standard and choice, while No. 2 is still in a less favorable position, showing occasional signs of weakness. We quote $19@$21, according to quality, while inferior to choice Gray Forge fetches from $18 @$20, all at tide-water. In Bessemer pig, another sale of 5000 tons of foreign is reported at a little less than $21 at tide-water, and $21 full is now quoted. In Spiegeleisen, sales of 2000 tons of lower grade are mentioned at $25.50@$25.75, while higher grades are quiet at $30.50.

Scotch Pig.—Business during the week has been dull at about our quotations. Arrivals are heavier this week, aggregating 2000 tons, and freights are cabled lower, 5@6s. from Glasgow.

We quote ex ship: Coltness, $23.75@$24; Langloan, $23.75@$24; Summerlee, $23; Dallmellington, $21@$21.50; Eglinton, $20.50@$21; and Glengarnock, $22.50@$23.

At the Exchange, the following slightly lower cable quotations were received: Coltness, 60s. 6d.; Langloan, 59s. 3d.; Summerlee, 57s.; Gartsherrie, 56s. 3d.; Glengarnock, at Ardrossan, 55s. 3d.; and Eglinton, at Ardrossan, 48s. 6d.

Rails.—Current business is small and unimportant. There are orders on the market for 50,000 tons of rails for delivery early in 1884; but as yet buyers and sellers have been unable to come to terms, buyers' views being in some cases as low as $36, which the mills show no eagerness to meet.

Old Rails.—Holders' views are still high, and business is limited, though inquiries are more numerous. We quote nominally $22.50@$23.

Scrap.—Spot stock and arrivals are light, and business is dull on the basis of $22.50@$23 ex ship for No. 1.

Philadelphia. August 23.

Pig-Iron.—Buyers still hold back, and sellers still refuse to make the concessions desired, to secure the placing of fall and winter orders. The situation has changed but little for the past week. Furnace-men are waiting for a demand which will at least prevent any further downward tendency, for which they say there is no room. Standard No 1 Foundry iron, tide-water quotation, $22@$23; Common, $21@$21.50; No. 2, $20@$21; ordinary makes, $19@$19.50. No large sales were closed this week. A number of negotiations are in hand, but buyers have no reason for purchasing largely, and sellers seem indifferent. Representatives of the stronger companies think buyers are making a mistake in failing to come forward when iron can be had at $17.50 at furnace, and fair No. 1 Foundry at $22. There are offers at $17 for Forge, and $21.75 for Foundry. Bessemer iron is quiet and firm at $21. Transactions for the week, 12,000 tons. Spiegeleisen, $25.50 and $31, according to per cent; sales, 4000 tons.

Blooms.—But few large buyers are around. Some sales took place at $56@$58 for Charcoal and $46@$48 for anthracite.

Merchant Iron.—Selling prices are unchanged; 2·10@2·15c. is offered; 2·15@2·20c. asked, according to size of order. The market is weak, and prices fluctuating. Manufacturers are not willing to sell good iron under 2·15c., and buyers think they can secure stocks later on at 2·10c. Small lots of Refined are firm at 2·20c.

Plate and Tank-Iron.—Plate-Iron is in fair demand for small lots, chiefly at 2·40c. for Angles, 3@3·25c. for Shell, and 4 4·25c. for Flange.

Sheet-Iron.—A fair number of small orders were placed at 4@4½c. for Common, and 6@6·50c. for Bloom Sheets. Galvanized is in good request, and large orders are in negotiation.

Structural Iron.—Makers report fair inquiry. Moderate business and firm prices at 3·50c. for Channels and Beams.

Steel Rails.—Prices are firm at $38@$38.50 for fall delivery, and negotiations are about closing for large lots for winter and spring deliveries somewhere from $36 up.

Old Rails.—Prices are quoted at $23 for Tees and $25.50 for Double Heads, with 50c.@$1 less offered. No sales heard of.

Scrap.—Scrap is dull and weak at $23@$25.

Pittsburg. August 22.

The Home furnaces are well sold up, but the outside furnaces are accumulating stocks, and the agents representing them are in town, making very attractive offers, but so far, without the desired success. There will be a steady consumption of iron during the fall; but thus far, consumers see no reason for buying more than a month or two ahead, notwithstanding some very tempting offers. Nearly all the business done is in from 100 to 200-ton lots. The highest sale of last week was for 1000 tons of Neutral Forge at $18. There were three or four sales of all-ore Forge at $19; Silvery, $18; Foundry Iron, $20@$21; Mottled Iron, $17. There are quite a number of inquiries for fall deliveries, and some fair offers, but transactions can not be closed excepting at concessions which Crop-makers are unable and unwilling to make. Crop-ends are without sale. Scrap is $13@$14 for cast bowings. Old Car-Wheels, $20. Selected Yard, $22@$23; No. 2, $21@$22. Spikes are 2·60c. Splice Bars, 1·90c. Track Bolts, 3@3·25c. Wrought Pipes are 70 and 10 to 75 off. Boiler Tubes are 57½ to 60 off. The demand for merchant steel is quite active, but for near-by requirements altogether. Prices are unchanged. Old Rails are quoted at $23. Stocks are absorbed. Muck Bars, $34. Merchant

iron is weak and dull, with indications of a stronger competition, which will probably depress prices to 1·80c. Nails are in fair demand at $2.90.

COAL TRADE REVIEW.

NEW YORK, Friday, Aug. 24.

Anthracite.

The future course of the coal companies is a matter which is discussed with considerable anxiety just now, and there is considerable complaint in the trade that the consideration of the interest of many of the magnates to sustain their operations in Wall street and other financial centers is more potent than the regard for the interests of the trade. Every effort is made on the part of some to create the impression that the anthracite coal trade is enjoying a period of unalloyed prosperity, which will warrant not only a continuance of the present heavy production, but also an upward movement in prices. A number of the New York companies, which are not forced to take extraordinary measures to meet current obligations, appear willing to face the situation as it is and take the course which a wise business policy dictates. Some of them are accumulating coal, having a large quantity afloat in this harbor, and a large number of cars standing on the tracks. Even with the concessions they may be willing to make, they can not market all their coal freely. If buyers merely held off because they believed that there would be a better chance to put in supplies later, it would be a good plan to put up the nominal circular prices, and scare the unwilling into ordering or make them pay more later on. The fact is, however, that the quantity of coal used by one important element in the trade is less than it was last year. So far as the Eastern manufacturers are concerned, it needs no more eloquent proof of their position than to point to the great auction sales of dry goods the other day. It is true that the East is the weakest spot in the country, but it can not be denied that throughout New York, New Jersey, and Pennsylvania the manufacturing industries are in a less degree restricting work. The West is loaded up with coal, and at Buffalo there are miles of loaded cars upon which advances have been made. It will not do, therefore, to argue that the Western markets can be stocked to harden prices elsewhere. In this vicinity, retailers have bought as much as they care to take for the present at June prices, and some of them have bought for delivery to the end of this month. With these facts before them, it is not astonishing that there are many who are unable to see that it would do any good to go on producing at the present rate and at the same time announce higher circular rates. The latter are out of the question on those sizes which come into competition with low-priced bituminous coals. For other sizes, it is possible only by curtailing the production, at least temporarily. The position of the coal trade to-day is not much better or any worse than that of any other leading industry, and the efforts to make the public believe that it is exceptionally situated can only react unfavorably upon it. Those in the trade know enough of the actual situation. A single effort to buy cheaply or to place a lot of coal with a buyer will reveal it. Those who want to buy will simply restrict their requirements, if an effort is made to put up the price without restricting the supply.

Bituminous.

There is nothing new in bituminous coal.

STATISTICS OF COAL PRODUCTION.

Belvidere-Delaware Railroad Report for the week ended August 18th:

	Week.	Year. 1883.	Year. 1882.
Coal for shipment at Coal Port (Trenton)	3,341	68,188	55,694
Coal for shipment at South Amboy	11,735	488,822	528,482
Coal for distribution	14,471	488,266	442,262
Coal for company's use	3,152	98,788	79,408
Total	32,699	1,142,064	1,105,846
Increase		36,218	
Decrease			

Comparative statement of the production of anthracite coal for the week ended August 18th, and year from January 1st:

TONS OF 2240 LBS.	1883. Week.	1883. Year.	1882. Week.	1882. Year.
Wyoming Region.

DIVIDENDS.

HOMESTAKE MINING COMPANY, MILLS BUILDING,
NEW YORK, Aug. 13, 1883.

DIVIDEND NO. 60.

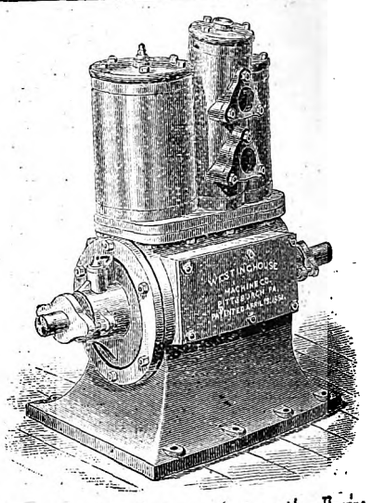
The regular monthly dividend of FORTY CENTS per share has been declared for July, payable at the office of the Transfer-Agents, Lounsbery & Haggin, Mills Building, 15 Broad street, on the 25th inst.
Transfer-books close on the 20th inst.
LOUNSBERY & HAGGIN, Transfer-Agents.

SAN FRANCISCO, Aug. 4, 1883.

THE BODIE CONSOLIDATED MINING CO. this day levied assessment No. 3 of 50 cents per share, delinquent September 10th. Sale day, October 10th. Same may be paid at the office of Laidlaw & Co., 14 Wall Street.
GEO. W. SESSIONS, Secretary.

WANTED.—A SITUATION; FIFTEEN years' experience in smelting, refining, and assaying lead, copper, and silver and gold. Speaks English, Welsh, French, and Spanish. Highest testimonials as to character and ability. Address,
C. M., Denver, Colo.

TIP TOP SILVER MINING COMPANY.



Location of principal place of business, San Francisco, California.

Location of works, Yavapai County, Arizona Territory.

NOTICE IS HEREBY GIVEN that, at a meeting of the Board of Directors, held on the 16th day of August, 1883, an assessment (No. 7) of TWENTY-FIVE (25) CENTS per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the company, Room 44, Nevada Block, No. 309 Montgomery Street, San Francisco, California, on all certificates of stock issued at San Francisco, and at the Farmers' Loan and Trust Company, Nos. 20 and 22 William Street, New York City, on all certificates issued at New York.

Any stock upon which this assessment shall remain unpaid on
MONDAY, THE TWENTY-FOURTH (24th) DAY OF SEPTEMBER, 1883,
will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on MONDAY, THE TWENTY-SECOND (22d) DAY OF OCTOBER, 1883, to pay the delinquent assessment, together with cost of advertising and expenses of sale. By order of the Board of Directors. HENRY DEAS, Secretary.

Office: Room 44, Nevada Block, No. 309 Montgomery Street, San Francisco, California.

MR. J. WENTZ WILSON, mining engineer, has left for Battle Mountain, Nevada, to examine properties in that vicinity. During his absence, communications should be addressed to him there.

THERE has been a "break" in the English steel rail market, and our contemporaries are deploring the fact that rails have been selling f. o. b. at £4 per ton. They do not see much of a chance for an improvement when the capacity is so much in excess of the demand, and, as the only way out of the dilemma, speak of the more extended use of Bessemer steel for other purposes than for rails.

IN spite of the fact that business is so depressed, the demand for the services of engineers of ability and experience is apparently greater now than it has been for some time. Applications come to us in greater number than usual, while those who are seeking employment are few. During the past week, we hear of two instances in which lead smelters are wanted, and to-day comes to us an inquiry for a chemist of experience, capable of doing the work required in a metallurgical establishment, in this case a gold chlorination-works.

WE are pleased to note that the long and vigorous agitation of the use of pyrites for acid manufacture is bringing out good results. We understand that the Davis mine in Massachusetts, whose ore was referred to in our issue of May 5th, is now producing at the rate of 2000 tons a month, and is selling not only in the Eastern States, but also in Baltimore. The company controlling the mine is in a position to contract for large quantities, and is taking the wise measure of doing all it can to aid manufacturers in putting up suitable plants for burning and running them.

DURING the present year, coke has made startling inroads into the foundry trade of anthracite coal in the Eastern and Middle States, where formerly the best grades of Lehigh lump were used to melt the iron in cupolas for machinery and stove castings. Connellsville, Snow-Shoe, and other cokes are so extensively used that not more than one quarter or one fifth of the quantity of anthracite used years ago is consumed. The low price of the coke and the comparatively stiff figures for the anthracite have, of course, brought about this revolution. It is likely that the difference between the price of the two grades of fuel will not remain so great for any length of time ; but the new rival is undoubtedly in many respects better suited for the purpose, and it will be difficult to dislodge it.

JUDGE BLATCHFORD has recently rendered a decision in the case of the Gramme Electric Company against the Arnoux & Hochhausen Electrical Company, which is of great interest to foreign patentees or purchasers of foreign patent rights. The Gramme Company controls the patents for the well-known Gramme dynamo-electric machine, and brought an action for infringement against the defendants, who pleaded that, as the Gramme patent in Austria had lapsed in 1880, the American patent expired at the same time. Judge BLATCHFORD sustained their view, thus confirming the position he has repeatedly taken under similar circumstances on former occasions. There can be no doubt that this interpretation of our patent laws subjects to a good deal of hardship those innocent buyers of foreign patents who are unacquainted with the danger they run, and often have no control over the manner in which the patent is handled in other countries. It increases the difficulties which foreign patentees must encounter in placing their inventions on our market, and teaches those who undertake the risk and labor of introducing them after acquiring the rights, that they must guard their movements with the utmost caution.

THE Bureau of Statistics has just issued its bulletin for the month of June, thus completing the figures for the fiscal year. A comparison of the data of this period with the year preceding it is of considerable interest, because in many respects the early summer of 1882 marked the beginning of the period of depression and liquidation, which, let it be hoped, has passed its climax now. Turning first to our imports of iron and steel, we abstract the following table :

IMPORTS OF IRON AND STEEL.

	1883.	1882.
Pig-iron, net tons	485,634	555,570
Castings, net tons	1,834	1,627
Bar-iron, net tons	58,435	75,197
Boiler iron, net tons	30	342
Band, hoop, and scroll, net tons	5,877	1,747
Iron rails, net tons	5,853	91,104
Sheet-iron, net tons	11,717	10,652
Old scrap-iron, net tons	70,964	177,020
Anchors, cables, etc., net tons	1,165	1,760
Steel rails, net tons	126,377	240,024
Steel ingots, bars, sheets, and wire	$12,204,945	$13,341,052
Machinery	2,228,732	2,027,340
Fire-arms	1,453,225	1,498,910
Cutlery	2,113,065	1,959,973

With a few exceptions, in which the increase is insignificant, there has been a falling off in our purchases from foreign competitors. The heaviest item on the list remains steel in various forms, as ingots, rods, etc., and the new tariff leaves no hope that there will be an early reduction in the figures. Old iron, pig, rail, and bar have all fallen off materially, and a comparison of the calendar years 1882 and 1883 will, we know, show a further decline.

The re-exports of foreign iron and steel are comparatively unimportant, the only heavy item being steel rails, of which 36,433 tons were reshipped in 1883, against 22,301 tons in 1882, thus bringing the net imports in 1883 below 100,000 tons.

The exports of iron and steel of domestic manufacture cut a sorry figure, the only redeeming feature being the growth of the export trade in machinery, edge-tools, fire-arms, and railroad stock, much of which, of course, went to Mexico. The following table gives the figures :

EXPORTS OF IRON AND STEEL.

	1883.	1882.
Pig-iron	$140,427	$194,411
Bar-iron	69,278	41,820
Iron rails	10,291	142,122
Castings	299,830	377,997
Car-wheels	184,614	118,195
Stoves	239,222	184,408
Locomotives	2,219,081	1,455,717
Stationary engines	191,208	111,199
Boilers	226,977	146,322
Machinery	6,223,029	5,525,948
Nails and spikes	354,065	335,820
All other manufactures of iron	5,918,610	6,084,365
Cutlery	102,100	92,031
Edge-tools	1,203,971	1,023,276
Fire-arms	1,097,934	907,957

Digitized by Google

The movement in metals has undergone considerable change during the year:

IMPORTS OF METALS.	1883.	1882.
Tin, cwts.	237,814	186,616
Copper ore, cwts.	527,394	163,819
" " value	$122,536	$157,708
Pig copper, lbs.	323,987	744,566
Manufactures of copper	$236,719	$315,475
Lead, net tons	2,751	3,777
Spelter, net tons	8,662	9,214
Sheet-zinc, net tons	1,650	2,132

It will be noticed that there has been a very large increase in the imports of tin; and this is rendered more striking when it is stated that the re-exports were only 1177 cwts. in 1883, against 23,144 cwts. in 1882, thus making the net supply 226,537 cwts. in 1883, against 163,472 cwts. in 1882. The imports of copper are insignificant, while ore, though increasing heavily in quantity, owing to the imports chiefly of Canadian pyrites, fell off a little in value. Spelter and sheet-zinc exhibit a falling off in the beginning of this year. The movement has now practically ceased, owing to the exceedingly low prices of the domestic article.

As the following table will show, our exports of metals have been satisfactory chiefly as regards copper:

EXPORTS OF METALS.	1883.	1882.
Copper ore, cwts.	112,923	25,936
" " value	$943,771	$89,515
Pig and old copper, lbs.	8,221,363	3,340,531
" " value	$1,293,947	$565,295
Manufactures of copper	$110,286	$93,646
" " brass	$287,847	$322,439
Sheet and pig-zinc, tons	426	750

It will be noticed that the value of the ore shipped abroad has increased more than ten-fold, and considering that the heavy export has begun only during the past few months, June alone being credited with $206,602, it will be understood that at the end of the year a very respectable tota will be reached. It must be a source of regret to all who have the growth of our home industries at heart to see upward of two millions of raw material leave the country to be manufactured elsewhere and distributed over the world, while we, with a plant unrivaled anywhere, and with superior skill in manipulating and shaping the metal into graceful forms, can not command a market for more than a fraction of the finished articles. Our miners have proved their ability to compete with any producing country in the world. The time has now come for our manufacturers to prove that they are able and willing to do their share.

GLASS FROM GRANULITE.

The manufacture of "pale metal" glass from the rock known as granulite has been carried on successfully by F. SIEMENS at Dresden, Saxony, and at Elbogen, Bohemia. The superiority of the glass and the great economy of production have secured to him a very large share of the bottle trade of the continent; the output of his works during the year 1880 having been about twenty-two millions of bottles, which has since nearly doubled in number annually.

It is now proposed to establish works in England to manufacture glass extensively from a deposit of granulite which has been discovered at Meldon, Devonshire, and using the Siemens process. Mr. SIEMENS, to whom a sample was sent, wrote approvingly of the quality as follows: "The small piece of granulite seems every thing we could wish for. If that kind of stone is to be found in large quantities, and of a uniform character, and easily to be got, it might prove quite a treasure, as it consists almost exclusively of silica and alkaline matter, with perhaps 15 per cent of alumina and but little iron."

These are the essential qualities of granulite for glass-making. The rock is generally classed as a member of the granite family. It consists mainly of quartz and orthoclase feldspar, and is either granular or schistose. It is sufficiently rich in the alkalies to fuse and to make a pale green glass, if a little lime is added sufficient to secure a perfect fusion of the quartz. The rock is nearly white, and in fact is known by the Germans as *Weiss-stein*. It should not contain much iron; the Saxon variety does not contain over 0·71 per cent. Similar rock, or rock which would serve equally well for the manufacture of glass, is found in Canada and in California, and probably in New England.

The economy in the use of the rock over the use of the ordinary sand and alkali is shown by Mr. SIEMENS, who states that, at his works in Dresden, the batch for ordinary green glass with granulite costs 8d. per hundredweight, and gives 93 per cent of glass; while the batch with sand costs 13d. per hundredweight, and yields only 67 per cent of glass; consequently glass from granulite costs only 8½d. per hundredweight, while that from the sand batch costs nearly 20d. or more than double, if calculated upon the glass. There are, besides, advantages in favor of the granulite in respect of fuel, labor, and wear and tear of furnaces.

In the prospectus of the English company, it is stated that the deposit at Meldon has been examined by W. F. RUTLEY, F.G.S., who finds it to be in quantities sufficient to supply any likely demand for glass manufacture in England for the next thirty years. It is proposed to put up the works at Swansea, and to connect the quarry at Meldon by a siding with the London and Southwestern railroad system by which the granulite will be taken to the port of Fremington, to be sent thence by water at small cost to the works at Swansea. The advantages of this location rest in cheap coal, limestone, and labor, with works already built, excepting SIEMENS'S continuous melting-tanks, which are to be added, a license having been obtained from Sir WILLIAM SIEMENS. The company proposes to make, not only bottles in large numbers, but glass castings, as substitutes for woods and metals. Among other articles, millstones, gas and water-pipes, and even railroad ties are enumerated.

These facts should stimulate a search in this country to determine whether deposits of magnitude of suitable granulite are favorably located for transportation to make their development practicable and profitable.

FROM HANCOCK TO ONTONAGON.

Special Correspondence of the Engineering and Mining Journal.

The superabundance of water, this year, has been helpful to many of the copper mines. The Allouez, Peninsula, and Wolverine have been especially benefited, although the first and last could hardly be said to be in want before. However, the Allouez, to do the work of the future, stands in need, quite possibly, of more water than has been available during the past few years. This mine had its regular set-back about the middle of July, by a fire in the stamp-mill, which threatened to prove a serious catastrophe. The blaze was quickly extinguished, and, excepting some incidental damages to the roof, the mill escaped without any injury. The record of the Allouez for June and July is the most satisfactory for years. The showing of mineral for June, nearly 112 tons, was the largest in the history of the mine, and, as I am informed from most trustworthy sources, was produced with an ease hitherto unknown. No. 3 shaft is in copper ground, and is able to take its share of hoisting other cupriferous ground which has formerly been done solely by No. 2. This makes the burden of No. 2 much lighter, or at any rate much more profitable. By economical and skillful handling, the mine is able to send more rock down to the stamps, and at distinctly less prices than ever before. This will be good news for the patient friends of the Allouez, and is thoroughly reliable. This mine has long been under a cloud, and has equally long deserved better than it has had. The ground is lean, scarcely ever at all fat, and very hard withal; the lode is very wide, the copper in small particles, and much has to be done for little; but its present facilities for work are very excellent; its hoisting and crushing plants are very complete; it has a new locomotive, and were its stamp building a little more steady, it would have nothing—except copper—to be desired. The Allouez is promising, though in fairness it ought to be said not immediately flattering. It has enough water at the stamps for twice as many heads, and can now do work for all there is in it. Its neighbor, the Wolverine, seems to be going higher in public estimation as it goes deeper into its well-charged lode, although the real value of the lode is yet a matter of hypothesis. It is publicly stated that this mine can produce copper at 10 cents per pound. But this must be taken *cum grano salis*: it may reach such a figure for a few days, or even a few months; but such a rumor must not be taken as any probable basis for calculating the future of the property. The output for July, however, was in excess of the Peninsula by about 31,000 pounds—a very creditable showing, indeed, although the aggregate for 1883 falls below the Peninsula by some 130,000 pounds. The Peninsula is putting in a new head of Ball stamps, and, with the additional capacity which this will insure, will push its way steadily to the front of the smaller mines. It is spending money quite freely in proving up the various unexplored belts which cover its property, but is more than paying its way, I understand, from the proceeds of the old conglomerate beds. The history of the Peninsula before its re-christening—say from 1865 to 1869—would be a profitable text-book for the directors of at least one other Lake Superior copper mine to study. The old Boston & Albany was ruined by excessive surface expenditure before the value of the beds had been thoroughly proved up, and a warrant for the outlay found in the tangible resources of the copper belt. In this, too, the Wolverine furnishes a good illustration of legitimate development, increasing its plant as it has found reason for such action in the actual showing of the mine.

The Calumet & Hecla is putting in a new hoisting-plant at the Calumet end, thus holding its jumbo as a canvass-backed curiosity, and introducing a horizontal Corliss to do the work for which the jumbo was originally designed. Improvements are also making at the Hecla engine-house, which connects with the hoisting and compressing machinery. The electric lights from each of the two poles are said to be visible from the decks of steamers shortly after clearing from Duluth. It is wrong to say that the Calumet & Hecla intends swamping the other mines when its new Leavitt stamps are ready for action. These powerful heads are put in to economize and facilitate the milling of the rock; and it is probable that this gigantic property, conscious of its ability to crush the backbone of its humble neighbors, if it comes to a case of dog eat dog, will pass them by as the larger Spanish mines do their modest competitors, content with its lion's share, and allowing each dog to have his bone. Of course, if the Western mines infringe too much, it may put in a rejoinder by way of an unprecedented output and unprecedented economy in the management at this end of the property; but for the present, at least, these are both improbable and irrelevant. Few corporations pay such wages as the Calumet & Hecla. Indeed, the wages question forms no stumbling-block at all in the path of the mine to the very highest financial success. The enormous reserves of the company do not make economy either in wages or construction essential to its annual dividends of $2,000,000, and it can not be truthfully said that economy is to any appreciable degree practiced. The stockholders do not seem to put in any disclaimer, although a very respectable company of speculators left it, not long since, to put their funds into telephone stock as being more remunerative and no less sure. But in the other mines, the wages fund cuts a very important figure, although by no means as important as before the introduction of power drills and compressed air. The relation of the construction account to the year's expenditures was at least casually presented in a former letter. The wages question has regulated itself, and needs now to be referred to

Digitized by Google

only as a matter of history. There has been a general reduction through the Houghton and Keweenaw mines of about twelve and a half per cent, although in several instances, where wages were already at hard pan, it falls somewhat short of this. A reduction in wages in Ontonagon would have been impossible, unless the miners had turned farmers, and I learn of no very considerable falling off in the year's expenditures in that quarter. It ought to be remarked, in passing, that the question of explosives is now one of importance approximating to that of wages. There is some incoherent talk of a combination among the mines to manufacture their own giant powder on the co-operative plan, and thus reduce the prices at which it is now maintained by powerful monopolies. A reduction in the cost of explosives, together with the reduction in coals which has already set in, would lift a burden from the mines, which, though so far not intolerable, is very embarrassing, and help them to undertake the future mining of copper on a basis of competition in the markets of Europe.

The Tamarack, which, you will remember, is making a vertical plunge of something over 2000 feet after the Calumet & Hecla conglomerate, is going steadily on downward to its prize; a little slowly of late, averaging not quite thirteen feet, but now again at its old pace of from fifteen to seventeen feet per week. It has already passed through several more or less heavily charged copper belts, at least one of which is worth working. The Allouez lode, which some were expecting would be struck very rich in the Tamarack, was passed at something over a hundred fathoms, but was pinched out to a mere sandwich. At the present rate of descent, the shaft will be half-way down by the close of the year; and in another year and a half, the Calumet & Hecla conglomerate will be tapped and the work of developing the property begun. There are some outsiders who still regard the scheme as chimerical; but the cost and the rate of descent have thus far been much within the estimates upon which the experiment was inaugurated. I am told that the ventilation thus far could not be improved, and, barring out the death of a Finlander who fell into the shaft several months ago, no accident has occurred on the property. The mine makes little water—none at all, I believe, after the first three hundred feet. Apropos of the Tamarack, it will be interesting to the readers of the ENGINEERING AND MINING JOURNAL to know that a cross-cut driven in the Osceola (in whose office reposes the management of the Tamarack) has opened up a belt which, under a test process of drifting, has furnished a considerable quantity of barrel and stamp copper, although the extent and value of the find are not as yet known—at least to me. The Osceola is laying the foundations for a new head of Ball stamps at its mill in Hancock, and will soon materially increase its output, which is already in excess of last year.

Very little is doing at the Phœnix, although the fabled bird is far from giving up the ghost. A party of virtual tributers, at the head of which is Hon. Charles Briggs, of Calumet, has the mine in hand for liquidating indebtedness. The mine is said to have produced over 450,000 pounds thus far in 1883; and if the output had continued uniform until the winter holidays, it would have reached a higher figure than any year since 1877. Doubtless, the mine would have continued to work more or less strong if the prices of January had been maintained; but the Phœnix has, for the present at least, been compelled to succumb under the pressure of an export market. It is said by trustworthy persons that better days are in store for the Phœnix; but it is hard work to recuperate after an onslaught of tributers has been made on the galleries of a mine, since tributers raise their funds as Indians do their trophies, by scalping their victims. The Phœnix has had an eventful history, and all who are acquainted with the history of Lake Superior mining will wish this old and finely situated property a future as remunerative as its past has been discouraging and disastrous. Its distant neighbor, the Copper Falls, has been selling at Boston for twenty-five cents; but there were no reports to your correspondent of Keweenaw people loading up very heavily even at that nominal rate. The mine makes a showing of mineral, however, which outstrips the Huron, Wolverine, Grand Portage, Hancock, and Phœnix, reaching, up to August, an aggregate of nearly 600,000 pounds. The cost of production is not high at Copper Falls; and if the yield were uniform, mining could be carried on at a comfortable profit. Your correspondent did this property a trivial but inadvertent injustice last June, by saying that the mine was about to put in a new head of stamps. The mine has two very fine heads of Ball's stamps, with an aggregate capacity of about 300 tons of rock per day. But one, however, has been running since early in 1881; the other is now at work also. Your correspondent makes this correction unsought and heartily, the mistake being a *lapsus calami*. The surface work at the Conglomerate is progressing at its usual pace and volume, but to what purpose must be shown by the sequel.

Over in Ontonagon, which is wonderfully beautiful and picturesque at this season of the year, the Nonesuch was practically idle when these notes were first written, but is now starting into life again. An Eastern syndicate was up while your correspondent was doing the copper country, and arranged to begin active operations at once. The Mass mine at that time had recently discharged forty miners, and was making no effort to keep the mine open ahead. Captain Chynoweth, the agent, then East, endeavoring to persuade the directors to open at least some small reserves, has since returned with instructions to carry on his stopes, but to do no sinking. Several antagonists of the belt scheme use the comparative failure of the Mass as a war-club for thumping the undertaking of our British cousins, since the Mass is sinking the Knowlton vein, the only thing in the belt system of which any thing at all is known. But this is unfair, since the action of the Mass people shows not necessarily that the Knowlton vein is too poor to pay (though it may be a very pungent hint in that direction), but that the Mass people are not willing to hand in enough contributions to attack the beds after the manner of the Pewabic, Osceola, and Allouez. I learn indirectly from England that the Belt stock is not finding much public favor, although I doubt not those who have gone into the enterprise will see it through. The machinery for the stamps is already landing at Ontonagon, and by the time it is *in situ* will have more or less copper to set it pounding. In case the Belt should prove a *fiasco*, it can never be charged against the integrity of American miners; for no disinterested miner was ever asked his opinion of the property. However, time will decide in emphatic tones whether our English relatives have paid too dearly for their whistle.

SPECULAR.

NOTES ON THE EXHIBITION AT DENVER.

Special Correspondence of the Engineering and Mining Journal.

The exhibition was opened this year on the 17th of July, when an address was delivered by Senator H. Miller. The exhibits were, as usual, tardily placed, and it was some time before all was in good trim. Though some counties which were here last year are conspicuous by their absence, the display is, on the whole, very good, and only needs an appreciative public. More space has been provided this year for machinery, but, though taken, has not been entirely filled.

The Lake County exhibit, as representing the richest district in Colorado, ought to be the first described; indeed, it is the first to attract attention, being very properly placed in front of the entrance to the exhibition building. Its value is very much enhanced by two large geological maps of the Mosquito range, lately issued by the U. S. Geological Survey. It would be well for each county and district to copy this plan in the future.

The case which is set apart for the exhibit of the Chrysolite mine is the most complete in this section, and is well worth careful study. It is divided into three sections, having in the center a splendidly executed plan of the mine by Mr. Howard Platt, a very expert draftsman. This plan shows the different properties belonging to the company and their contours. The properties consist of about ten claims. There are also five geological sections, very interesting as showing the replacement of the limestone by the ore-bodies, and also the points where the gray porphyry dikes have cut through all the separate formations into the ore-body. These sections also show very plainly that puzzling phenomenon, very characteristic of this mine, where bodies of limestone lie separated from the beds in irregular masses, much replaced by ore and surrounded on every side by porphyry. The different formations cut through by the gray porphyry dikes are the white porphyry, Cambrian quartzite, Silurian limestone, parting quartzite, and Carboniferous limestone. What are called the second and third iron deposits lying in the limestone are shown, from which some rich ore has been taken. The whole country of the mine is made up of masses of white porphyry. In the cases are, first, specimens of block porphyry, dike porphyry, nodules of dolomite, dolomite sand, quartzite, limestones, etc. Secondly, curious specimens of iron chert; galena from the second iron deposit, in the Carboniferous limestone, and containing 120 ounces of silver per ton; galena from the third iron deposit, in the Silurian limestone, from which deposit some rich ore has lately been taken. Thirdly, rich galenas, containing, in some cases, over 400 ounces per ton; silver lead ores associated with barytes; carbonates of lead and silver containing from 100 to 300 ounces of silver per ton, and from 40 to 60 per cent of lead; sand carbonates containing from 1000 to 2000 ounces of silver per ton; and a specimen of chloride assaying about 5000 ounces of silver per ton, and 40 per cent of lead. There is also a photograph of the mine buildings and neighborhood.

The Silver Cord mine has also a wonderful and splendid mineralogical display. Among the most notable are some specimens of concretionary calcite, some of the concretions measuring three inches across, and being beautifully radiated. This mine shows many splendid specimens of that very rich silver ore embolite, a bromo-chloride, two in particular, consisting of ochreous carbonates, speckled all over with fish-like scales of embolite and cerussite. One specimen of a carbonate of lead shows a remarkable structure resembling petrified wood. A curious specimen of oxide of iron is exhibited, having a botryoidal structure, resulting from the decomposition of a carbonate. There are some fine cut and polished specimens of kaolin, some colored with various minerals, and some colored with copper. Of the hard gray carbonate which forms the staple shipping ore, there is one block weighing a ton. Some beautiful dendrites, due to manganese, and some fine specimens of galena, hard carbonate, incrusted with chloride of silver, sulphato-carbonate of lead containing 103 ounces of silver per ton, help to make up a truly elegant exhibit. As curiosities also, there are specimens of malachite staining siliceous nodules in a sand carbonate, and specimens showing galena and carbonate of lead in contact.

The A. Y. mine shows some of the best specimens in the exhibit, a number of them consisting of highly crystallized pure carbonate of lead, though generally colored a rich brown by iron oxide. One or two in particular are rendered more beautiful still by fine foliated native silver being scattered over them. Some masses are composed of crystals more than an inch long. Some specimens show the lead crystals on brown iron oxide. Among the carbonates from this mine may be mentioned some specimens of an amorphous carbonate of lead, closely resembling the ordinary white-lead of commerce. There is a fine specimen of anglesite (sulphate of lead); also galena, containing from 5 ounces of silver per ton, and 70 per cent of lead. Some curious specimens are shown of galena laminated with iron pyrites and zinc-blende. There are some truly splendid specimens of galena covered with native wire-silver; also black sand carbonate, 60 per cent of lead, disintegrated iron pyrites crystallized in cubes and octahedrons, and galena associated with carbonate of lead. A specimen of limestone, showing the chemical action of water very plainly, has been taken from under the ore-deposit.

In this exhibit, there are also a number of splendid specimens from the celebrated Mike & Starr mine, consisting of galena, with iron and copper pyrites, carrying 520 ounces of silver and 15 per cent of copper, and a specimen of iron pyrites in gray porphyry, containing small quantities of lead, silver, and gold, which, according to many authorities, are representative of the original rock whence all the riches of this extraordinary region have been derived. Some vanadates of antimony are also exhibited.

The Robert Emmet mine shows carbonates containing 175 ounces of silver and 60 per cent lead. The Ready Cash is represented by free-milling ore containing 400 ounces of silver and 10 ounces of gold. Some nearly pure hematite ore is worth mention, in view of the late meeting at Denver to organize an iron smelting establishment.

The Yankee Doodle mine shows a number of good sand carbonates and ocher ore containing 556 ounces of silver per ton, and 61 per cent lead, and 202 ounces of silver per ton and 25 per cent lead respectively. This mine also shows some fine blocks of different colored hard carbonates with over 150 ounces of silver per ton, and specimens of a fine-

Digitized by Google

grained, peculiar quartz, etc., overlying the ocher ore. The Henriett mine exhibits sand carbonates with galena, 90 ounces of silver per ton, and crystallized galena and lead carbonate assaying 100 ounces of silver per ton. Also, a grand block of galena, showing the passage into carbonate, fine-grained galena showing curious action of water, and a block of hard carbonate containing large rhombic crystals of cerussite.

Specimens from the Carbonate mine are distinguished by nearly all showing a quantity of embolite on their surfaces. Those worthy of special mention are a breccia of limonite and other oxides of iron covered with the above-named mineral, and a carbonate also showing embolite. The ores shown for this mine run about 400 ounces of silver per ton.

The Iron Silver mines show an interesting series of different-colored sand carbonates in bottles running from four up to 710 ounces of silver per ton; a curious and fine specimen of calcite in calcareous limonite; specimens of native sulphur; and large blocks of rich hard carbonates and galena, showing that the ore exists in large masses. Dendrites and leadhillite are also noteworthy.

Little Pittsburg mine shows galena running from 90 to 800 ounces of silver per ton; and Little Chief mine hard carbonates and galena with embolite assaying from 90 to 500 ounces of silver per ton. The Long & Derry mine is represented by some rich ore with chloride of silver; the Dunkin and Wolfe Tone mines by rich galena; and the Cyclops mine by rich carbonate ore with sulphuret of silver up to 1100 ounces per ton. The Harrison Reduction-Works exhibit samples of matte, speiss, and materials for reducing ores. There is some gold ore from the Double Decker mine, containing 35 ounces of silver per ton; also some horn-silver from the Big Pittsburg, azurite from the Highland Chief, and a beautiful specimen of chalcedony on amethystine quartz. The Matchless mine shows, generally speaking, the richest collection of ore in the Lake County exhibit, although mineralogically poor. It consists chiefly of hard carbonates in immense blocks, and showing, in many cases, embolite, and of a peculiar argillaceous ore which, when taken out of the mine, is in a wet and plastic condition. One specimen of this ore (a black variety) is made up into a large square brick. Its richness is sometimes very great, one sample assaying 2750 ounces of silver per ton. Many others assay over 1000 ounces of silver per ton. There are also some fine large pieces of horn-silver, assaying about 23,000 ounces of silver per ton; and a curious block of flint, interesting as showing the probable presence of thermal waters during the deposition of the ore.

The Robert E. Lee has a few very rich samples of hard and sand carbonates, but nothing very striking. The commissioner for Lake County, Mr. N. H. R. Read, who kindly furnished me with all particulars, has compiled the following list of the production of that region up to July 1st, 1882, which may be of interest as showing the rapid development of the Leadville camp during the last few years:

Yield from 1860 to 1873, gold from placers	$6,400,000
Yield from 1874 to 1875, gold and silver	258,000
Yield for 1876, gold, silver, and lead	85,000
Yield for 1877, gold, silver, and lead	555,000
Yield for 1878, gold, silver, and lead	3,153,000
Yield for 1879, gold, silver, and lead	10,333,000
Yield for 1880, gold, silver, and lead	14,187,000
Yield for 1881, gold, silver, and lead	13,170,000
January 1st to July 1st, 1882	7,817,000

The Colorado Machinery Company has one of the best exhibits in the mining machinery department. It exhibits the celebrated Deane pumps in motion, one capable of delivering 150 gallons per minute; also a large and good assortment of tubes and pipes for various purposes from the National Tube-Works Company, Chicago; a new fan blast ventilator by the Chicago Ventilating Company; patent noiseless exhaust fans by the Boston Blower Company; patent pulverizers and an Embrey concentrator by Stephen P. M. Tasker, of Philadelphia, Pa. There are also mine supplies in the shape of tubs, mine cars, slag-barrows, Fairbanks scales, etc., and a model of Huson's patent endless wire rope tramway.

Among notable new things exhibited this year none is more deserving of notice than a new drill called the Randall chamber drill. This is one of the newest "notions" of the West, as it is also likely to prove one of the most useful. It has borne the test of hard work with credit. The inventor, Mr. Randall, of Pueblo, claims in his specification that it is an improvement on the chamber drill patented by E. J. Williams, in 1879. His object is, to quote his own words, "to provide an improved means for enlarging the diameter of a drill-hole at the bottom thereof." The cutting-bit is fitted to the drill-stock by a strongly made tenon, which fits into a recess in the stock provided with a knuckle or ears, being held there by a pin passing through both. It is so made that the force of the blow is received by beveled shoulders on each, situated at the front and back of the drill. It is claimed that the blow is distributed or conveyed more nearly to the center or axial line of the drill-stock than in any other drill now constructed for the same purpose. When the drill enters the drill-hole, the bit is on a line parallel with the drill-stock; but in practice, it is at an inward angle of about 30 degrees, and cuts outwardly as the drill-stock is rotated, thus quickly cutting out a chamber at the bottom of the drill-hole. The peculiar construction of the curved end of the cutting-bit materially assists its operation. I hope to say something as to the other exhibits in another number.

A. COPELAND.

August 23, 1888.

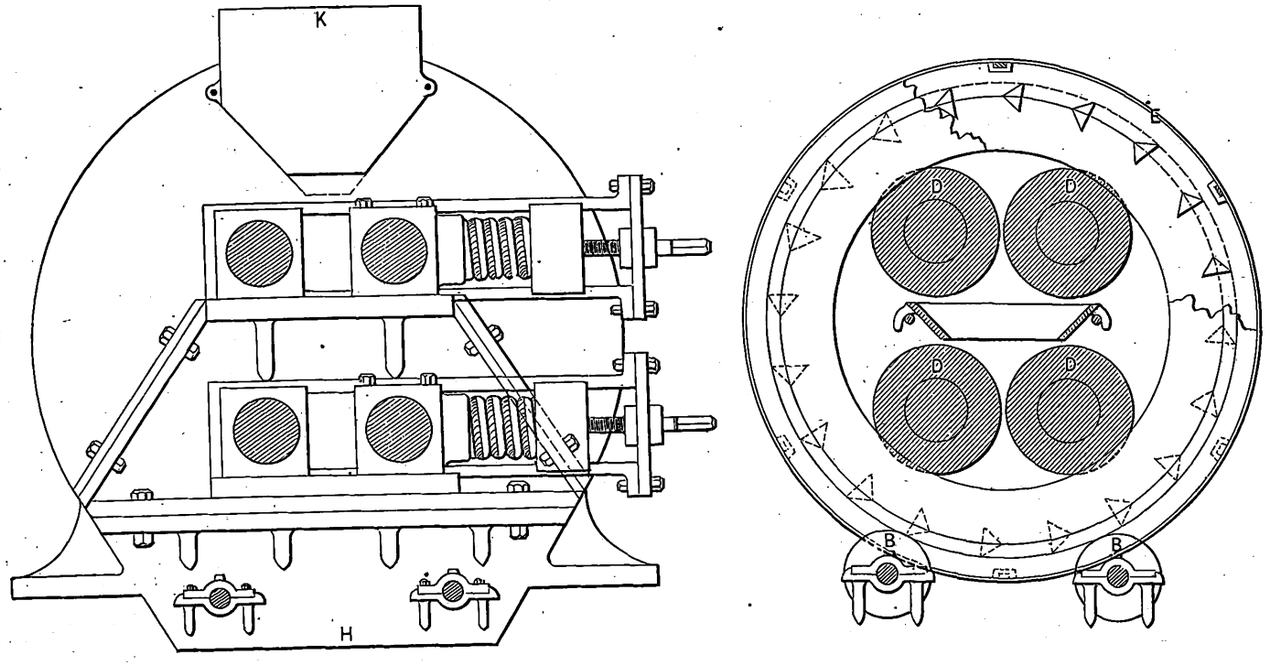
A TUNNEL UNDER AN IRON MILL.—The last stroke of work on the big tunnel, 1650 feet long, under Jones & Laughlin's Iron-Works, Pittsburg, has been completed. The tunnel was constructed by the Vanderbilt Pittsburg, McKeesport & Youghiogheny Railroad. Its cost will be $500,000. Over six hundred men were employed on it for a year. The tunnel is one of the engineering feats of the day. The roof is only a few feet below the top of the mill floor, where massive rolls, hammers, and hundreds of men were working. The mill is the largest single mill in the United States, and none of the buildings was injured, and work was not delayed an hour. The ground through which the tunnel passes was mill cinder and slag. For over one hundred feet the slag was so hard it could not be blasted. Heavy weights were dropped on it, and the broken pieces buried in holes where they fell, as they could not be moved, the masses were so large. The road opened for a distance of sixty miles on Sunday for freight traffic.

THE GATES PULVERIZER.

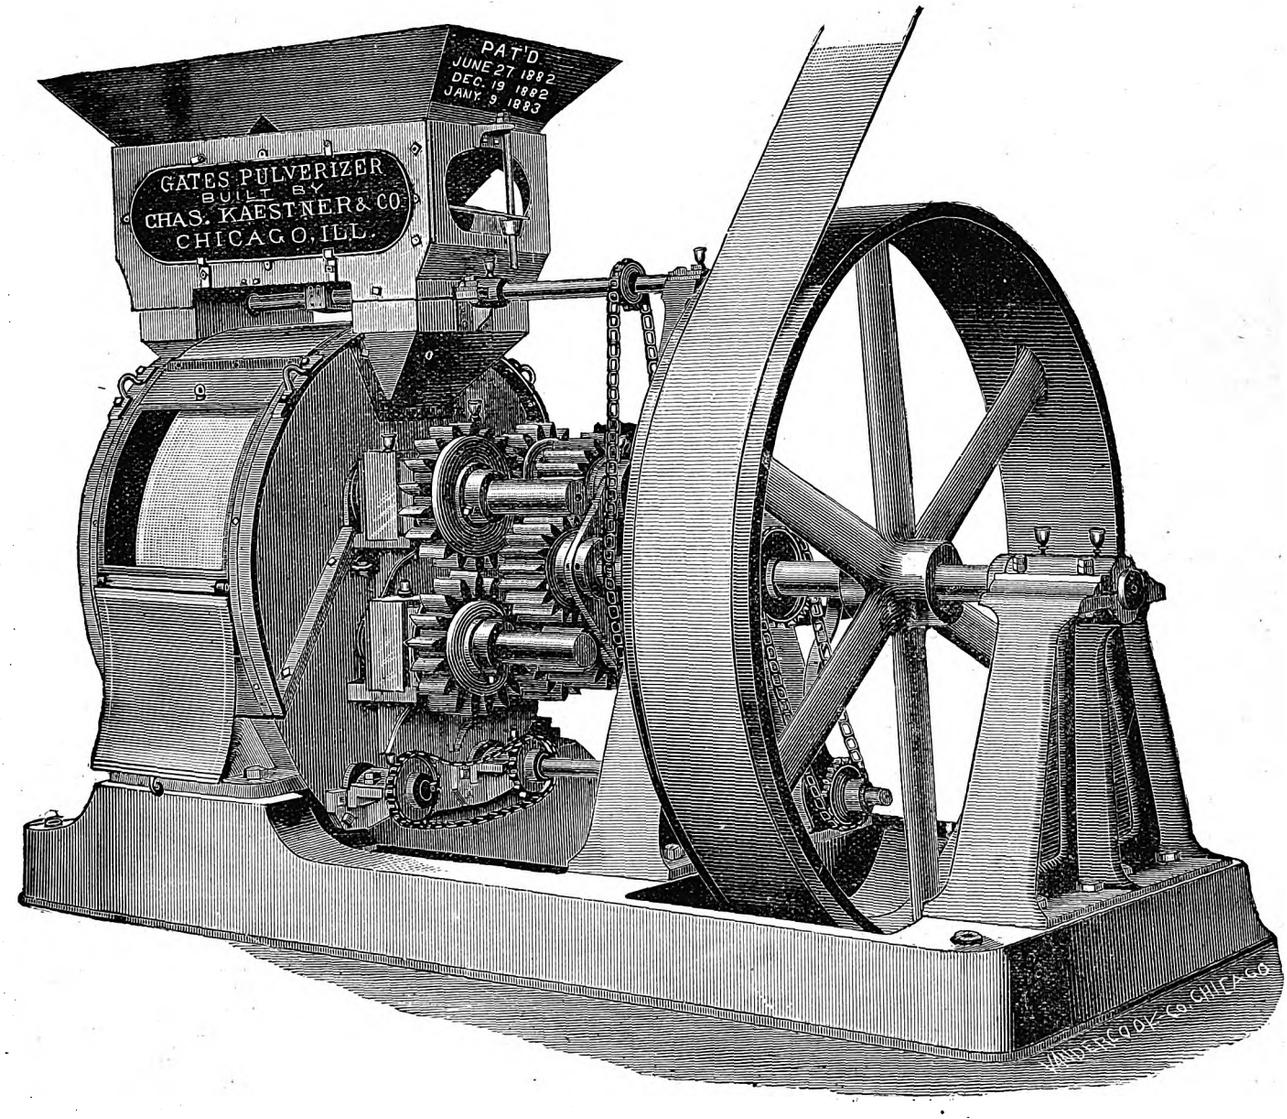
We have repeatedly referred to the movement now in progress in milling circles, to crush ore that must be roasted previous to leaching or amalgamation, in favor of rolls as a substitute for stamps. We need not, therefore, rehearse the points which favor the substitution of one class of machinery, and propose simply to call attention to the latest design, brought forward by Messrs. Charles Kaestner & Co., of Chicago, which we illustrate in the accompanying drawings.

As shown in the section and side elevations, the pulverizing mechanism consists of two sets of rolls *D*, placed one above the other, and driven by a single outside gear-wheel on the pulley-shaft. After having been brought down to a suitable size in ordinary crushers, the material to be pulverized is put into a double hopper, from which it is distributed by a simple self-feeding arrangement, shown in the drawing, to the upper set of rolls. Passing through these, it drops on the table shown in the section, and is delivered to the lower set of rolls, by which the bulk of it is reduced to the desired size. Within certain limits, the distance between the individual rolls of a set may be regulated by placing flat pieces of steel between the journal-boxes. The tension on the springs forcing the rolls toward one another, may be regulated by the screws shown in the elevation. The wearing surfaces of the rolls themselves are shells of chilled Franklinite iron, which are held in place by bolts. The material dropping through the lower set of rolls falls upon a revolving screw having elevator buckets on the inside, within an inch of its surface. That portion of the material which does not pass through the screen accumulates with the finer material until the buckets are able to scoop it up and return it to the top set of rolls. The screen is driven by chain from the main shaft and runs on the friction-rollers *B B*. The entire crushing mechanism is inclosed in a casing, the journals, however, being placed out of the reach of dust. We have had occasion to examine the workmanship of the pulverizer at the establishment of Messrs. Kaestner & Co., and noted that it was substantially and well built.

One of the principal objects of the design, aside from that of reducing a maximum of material to the desired size with a minimum of wear and expenditure of power, has evidently been to render the machine compact, and to do away with separate screening and the nuisances of dust and attendant losses. The pulverizer is now in use at the mill of the Portland Consolidated Mining Company, Deadwood, D. T., and the Northwestern Terra Cotta Works, Chicago. We shall soon be in a position to report on its performance at the former establishment.



SPLICING THE BROOKLYN BRIDGE CABLE ROAD ROPE.



Recently the rope of the Brooklyn Bridge cable road, which is now nearly ready for regular business, was spliced. The rope is 11,600 feet long, or about two miles. Its weight is 31 pounds per foot, which gives it 35,900 pounds for a total weight. The diameter is 1¼ inches, and it has a breaking strength of 50 net tons. The center of it consists of a tarred hempen rope or cord; around the center six strands of wire are coiled, and each strand consists of 19 wires, so that the cable consists of 114 wires, compactly and stoutly wound spirally about a hempen center. The most particular part of the work of rigging this traction cable was uniting the ends so as to make it endless. The cable was furnished by the Roebling wire factory, and when the work of laying it reached the point where splicing was necessary, application was made to the factory for a man skilled in splicing. The best man that could be had was asked for. The best man was at the time in California, whither he had gone to splice some cables for the Cable Street Railroad Company of that city. Engineer Martin was looking about for some other splicer when he learned that the man who had gone to California was on his way back. By waiting forty-eight hours, the man that he wanted was secured.

The splicing of such a cable, as has been remarked, is a pretty nice piece of business. It has been performed on the bridge cable so neatly, that no one can discover where the two ends come together. In order to keep watch of the spliced parts, they have been painted white. The white place is 160 feet long. As nearly as the process of splicing can be described here, it was done in this way: The ends of the cables were drawn 80 feet each way from the point where they met—that is, they were lapped that distance. Then one of the six strands was uncoiled for the distance of 80 feet. Another strand was uncoiled for 68 feet, another for 56 feet, and so on for the whole six, each being 12 feet shorter than the other. This process was observed on both ends of the cable. Then the strands thus "shingled" were intertwined so as to restore the size and shape of the original cable. In order to accomplish this, the hempen core of the original had to be taken out by winding it outward along the trend of the original twist. As each strand of one end was laid about its companions of the other end, its extremity was ingeniously pressed in toward the center from which the hempen core had been removed, so that it is not seen, nor can it be found except by the closest tracing. To all appearance, the cable was made endless at the factory. The engineers of the bridge have been very much interested in the work of making the splice, they having never before witnessed a like operation.

THE DUTY ON CHARCOAL IRON.—A letter was received at the Treasury Department on the 24th from the Champion Horsenail Company, of Appleton, Wis., protesting in strong terms against such a construction of the tariff law as shall preclude from the privilege of entry at the rate of $22 per ton all charcoal iron irrespective of shape or size. This letter is the first one brought out by Acting Secretary French's letter of the 17th inst. to Secretary Swank, of the Iron and Steel Association. In that letter, the acting secretary said the Department was inclined to hold that the concluding proviso of paragraph 148, regulating the duty on charcoal iron, applied only to the kinds of iron mentioned in the paragraph, and not to round iron in coils or rods, or to iron rivet, screw, nail, and fence wire rods in coils or loops, when manufactured by the use of charcoal. It appears probable that the department will hold that, if an importer declares that the wire rod brought in by him is, to quote the letter, "intended for or adapted to the manufacture of rivets, screws, nails or fence wire," it must be admitted upon payment of a duty of $\frac{4}{10}$ of 1 cent per pound, instead of $1\frac{4}{10}$ cents per pound. Once admitted, the iron may, of course, be used for any purpose to which it can be applied.

THE NICKEL PLATING PATENT.

The decision of the United States Court for the Southern District of New York, Judge Blatchford presiding, sustains once more, goes a little farther, and gives a still broader interpretation to the Adams patent than had been given at any previous trial. Judge Blatchford holds substantially that Adams was the first discoverer of a practical method for electro-plating with nickel, and his patent secures to him practically a broad monopoly of the art, and of all articles electro-plated with nickel. The patent in question was granted to Isaac Adams, Jr., August 3d, 1869, and the two principal claims read as follows:

1. The electro deposition of nickel by means of a solution of the double sulphate of nickel and ammonia, or a solution of the double chloride of nickel and ammonium, prepared and used in such a manner as to be free from the presence of potash, soda, alumina, lime, or nitric acid, or from any acid or alkaline reaction.

4. The electro-plating of metals with a coating of compact, coherent, tenacious, flexible nickel of sufficient thickness to protect the metal upon which the deposit is made from the action of corrosive agents with which the article may be brought in contact.

The defendant, Pendleton, obtained a patent September 28th, 1880, for what he claims as a new and entirely different mode of plating with nickel. His claims are as follows:

1. In the art of nickel plating, an acid solution of acetate of nickel, consisting of oxide of nickel and acetic acid, said solution having an excess of acid.

2. The method of making acid solutions of acetate of nickel, consisting in slowly digesting oxide of nickel and acetic acid with or without heat, so as to have an excess of acid in the solution, substantially as described.

The court held the Pendleton process to be merely the chemical equivalent of the Adams process, and accordingly gave judgment for Adams, with injunction and an account.

MECHANICAL PUDDLING.

By J. G. Danks.

My purpose in this paper is not to treat the science of puddling generally, but merely to sketch the history of mechanical puddling, the difficulties encountered, and the manner in which they have been overcome. It is necessary first to describe briefly the old or hand system of puddling, as it may assist in understanding the difficulties to be met in performing the work by machinery. Puddling is the process in most general use for converting cast into wrought-iron, by first melting and then agitating the metal while kept at a high temperature; in which operation it is deprived of its carbon, silicon, and other impurities.

The process was first introduced by Henry Cort, in England, in the year 1780. In partnership with Samuel Jellico, at Fontley, in Southampton, he worked out this problem, which was at that time the most important step ever taken toward increasing the quantity and reducing the cost of manufacturing iron.

The bottom and sides of the puddling-chamber in Cort's furnace were lined with sand; and as the removal of silicon is one of the chief objects of the puddling process, it will be readily seen that one of his worst enemies (sand) was present at all stages of the operation. Notwithstanding this, the advantage of his invention to the manufacturing interests of England may be partly seen by the following figures. The total amount of iron manufactured in 1720 was about 12,000 tons, and at the time of Cort's patent (1780) about 90,000 tons, which in 1820 had increased to 400,000 tons, an increase due almost exclusively to Cort's invention. Although he had added millions of pounds sterling to the wealth of the kingdom, and opened the way for the employment of hundreds of thousands of men, the only recognition his services received was the empty honor of being a great inventor and the little estate now occupied by his moldering remains in Hampstead churchyard.

The first important improvement subsequently made in puddling was the invention of Samuel B. Rogers, consisting in the substitution of iron plating to the bottom and sides of the puddling-chamber, covered to a depth of ten or twelve inches with a rich oxide of iron, instead of sand. The plates are so constructed as to allow a free circulation of air, to prevent overheating. This oxide bottom not only permits the working of the iron at a much higher temperature than was possible on the sand bottom, but is itself a valuable agent in the removal of the carbon, silicon, phosphorus, and other impurities contained in the crude metal. The invention of Rogers was fully as important to the trade as that of Cort, yet the most substantial benefit we hear of his receiving was the nickname of "Old Iron-Bottom," by which he was known all over England. But little change has taken place in the process of puddling by hand since the latter invention was introduced; and although it is, in a scientific point of view, one of the most interesting operations in iron manufacture, it is also the most slavish and exhaustive labor to those engaged in it.

The earliest authentic records I find on mechanical puddling are the patents of Mr. Walker and Mr. Warren, of England, who, in the year 1853, took out a patent for a rotating cylinder lined with fire-brick. The axis of the cylinder was inclined to a horizontal axis of rotation, so that, as it revolved, the fluid metal was caused to flow from one end to the other. I am not aware that they ever built a furnace so as to test their ideas in practice. In 1856, Mr. Samuel Danks (the writer's father) filed a caveat in the U. S. Patent Office for a revolving puddling-furnace, and he had a furnace nearly completed in Mount Savage, Md., when the panic of 1857 caused the abandonment of the work for the time. In 1859, Mr. W. Tooth, of London, England, took out patents for a mechanical puddling-furnace, and was given every facility for testing the apparatus by Mr. William Menelaus, of the Dowlais Iron-Works, in Wales, where a complete forge was erected, and some good iron is said to have been produced. The lining used in these furnaces was either fire-brick or gannister, and Mr. Menelaus stated that the latter was found to be the best material he had tried. In 1863, Mr. Tooth and a Mr. Yates obtained additional patents for improvements in the process, all of which were tested at the Dowlais Works. In 1867, after having spent upward of $150,000 in experimenting, it was abandoned. Mr. Menelaus, in a paper read before the Institution of Mechanical Engineers, gave a description of their failures, which were mainly due to the want of a good lining for the puddling-chamber. Afterward, when showing a number of prominent iron-masters through the Dowlais Works, he pointed to the corner occupied by these furnaces as the "burying-ground of mechanical puddling."

It is important to notice that up to this time the only lining used in mechanical puddling was a highly siliceous one (like that used by Mr. Cort in the first introduction of hand-puddling), which would be readily dissolved by the molten metal and the oxides with which it was constantly coming in contact. Under these circumstances, it was found to be practically impossible to remove the impurities from the metal sufficiently to insure a good fibrous iron. Nor was this all; the character of the lining material was such that, when the iron was formed into a ball, its weight constantly broke the lining down, so that it was proved to be unfit to withstand either the chemical or the mechanical action to which it was of necessity subjected. An attempt was made to use an oxide of iron lining in the cylinder; but from the manner in which it was put in, it was evidently an oxide too high in silica for the purpose; or, if an oxide of sufficient purity were melted upon an initial lining of silica, sufficient of the latter would be dissolved during the melting to render it worthless.

During the time when these experiments were carried on in England (between 1863 and 1868), Mr. Danks moved to Cincinnati, Ohio, to remodel the old merchant mill on East Front street, and adapt it to the manufacture of iron rails. Here he again revived the question of mechanical puddling, and had obtained patents for a lining which, it is believed, would answer successfully all the requirements of use. In May, 1868, a small experimental furnace was built, with a capacity of working only about 300 pounds of iron at one charge, being thus limited by the machinery at hand to deal with the iron. Six hand-puddling furnaces were in use in the mill at this time, with the usual complement of workmen; and while the new furnace was approaching completion, the comments made by those engaged in the hand process were not encouraging; for they were, with few exceptions, opposed to any attempts to perform their labor by machinery.

Briefly, the new furnace consisted, first, of a fire-place about four feet square, the outer shell of which was made of iron plates, lined with fire-brick. Adjacent to this was the revolving cylinder, about three feet long and four feet in diameter, with a contracted opening at each end. One end of the cylinder was made to fit close against the fire-place, and the other provided with an adjustable elbow-piece, forming a tight joint with the cylinder end and also serving as a connection between the cylinder and the chimney, by which the waste gases escaped. The cylinder was mounted on four rollers, the end joints kept tight by a strong iron prop which forced against the shiftable elbow-piece, the latter being also provided with a side prop holding it firmly in position while the furnace is at work. The cylinder ends were kept cool by jets of water. The bridge casting, the bridge and door rings, also the front of the shiftable piece, were kept cool by water circulating through them. The fire-place was provided with a bridge-wall reaching half-way up the opening in the cylinder end, to prevent a mixture of the fuel and iron, but leaving a free passage for the gases through the furnace. The fire-grate was also provided with two blast-pipes respectively, for forcing air underneath and over the fire. The bottom blast entered the ash-pit and found its way up through the burning fuel. The top blast entered an air-space formed over the roof of the furnace, and was admitted to the furnace proper through a finely perforated brick arch, as nearly over the bridge-wall as possible. Each blast-pipe was provided with a valve under the control of the puddler. The advantages of forced blast in this form of furnace are many; chief among them are, first, a higher temperature than can be obtained by natural draught; and, second, that a slight pressure of flame may be kept in the furnace, which prevents the entrance of cold air at the cylinder joints, thereby avoiding not only a reduction of the temperature of the furnace, but a waste of iron by oxidation. The cylinder plates are ribbed on the inside so as to hold the lining, and the machine was rotated by a small steam-engine. When every thing else was ready, and the cylinder revolved a number of times, the lining was put in. This was done by first mixing pulverized Iron Mountain ore into a stiff mortar with about six times its bulk of thick lime-cream in a grinding-mill, consisting of a revolving pan and two heavy iron rollers, and with this material covering the ribs of the cylinder plates to the depth of one inch, making an average thickness between the ribs of four or five inches. The lower half of the cylinder was first lined, a good surface being put on it with a trowel, and the whole was then thoroughly dried, by building upon it a wood fire. The cylinder was then turned a half-revolution and the lining completed and dried. This was called the initial lining, and was only used to protect the plates, while the real or working lining was put in.

The furnace being now fired up slowly, a quantity of roll-scale or hammer-slag was first melted so as thoroughly to glaze the initial lining. A large quantity of pulverized ore and some light wrought scrap were now put into the cylinder and melted—the cylinder having been revolved slowly during the melting. After melting, the rotation was stopped and a quantity of dry lumps of ore thrown into the bath, serving the double purpose of presenting a rough surface to assist in agitating the iron, and also to hasten the cooling of the liquid oxide. After hardening sufficiently, a further quantity of ore and scrap was thrown in and melted; this operation being repeated about five times, usually completes the lining. The vitreous coating thus formed is very hard, and I never knew of its breaking down after once being cooled, except at the openings at the ends of the cylinder, where it is thin. The lining gradually wears away, but it is easily repaired and the entire lining need never be taken out unless for some necessary repairs to the plates.

When the furnace was put to the test of puddling iron, the ridicule so lavishly heaped upon it by the men ceased, a lively competition ensued, and it became evident that they had laughed too soon; for the machine had not been in operation many days before it produced seven charges of iron in less time than they could produce six by hand, and required less than one fourth the amount of manual labor, although employing

Digitized by Google

the same number of men. The quality of the iron was found to be superior in every respect to that made by hand.

This furnace was experimented with for some time, and then, with the view of puddling larger heats and still utilizing the old machinery, two larger ones were built, in which the diameter of the cylinders was about the same, but the length increased to about six feet, it being the intention to divide the charge into two or more balls. This was attempted by leaving apertures in the cylinder plates, through which pieces of soapstone or other refractory material could be inserted, for the purpose of breaking the iron asunder as the furnace revolved. Large lumps of iron ore were left projecting high above the general level of the lining; cast-iron projections, covered with a thin layer of the initial lining, were inserted; but all gave a good deal of trouble, and were finally abandoned as impracticable.

In carefully watching and testing the product of these two furnaces, a much more serious difficulty presented itself. In a cylinder so long in proportion to its diameter, the end next to the fire-grate was always much hotter than the other, and the iron at this end was always the best, thus producing two qualities of iron in each charge. Added to this lack of uniformity (which was not met with in the small furnace) was the labor of separating the iron. There seemed no way left to adapt the system to existing machinery; in fact, experience indicated that the farther we departed from the old method of making the iron into a number of small balls, the better would be the results. Accordingly, furnaces were built with cylinders six feet in diameter and four feet six inches long, in which the entire charge was made into one ball. With slight alterations, the old squeezer was made to take these balls of 600 pounds, and the iron was found to be perfectly uniform. The results obtained were so satisfactory that in 1870 the company authorized the removal of all hand-puddling furnaces as fast as machines could be built to replace them.

One result constantly met with was the subject of much unfavorable comment among those who had not investigated the subject. It was the fact that, instead of the usual loss of from ten to fifteen per cent in weight by hand-puddling, there was a gain of from five to eight per cent; that is, out of 500 pounds of pig-iron charged into the furnace, there were obtained in puddled bars from 525 to 540 pounds. The gain often ran up to ten per cent, but the figures given will represent a fair average.

I will now describe the operation of puddling by machinery, in which we shall find, at least, a partial solution of the above-mentioned seeming impossibility. Puddling is essentially a refining process, and as the refining is best accomplished while the iron is in a fluid state, a gray pig is preferable to a white pig, because it may be kept fluid as long as desired, this property being chiefly due to the amount of silicon it contains. White iron, which usually contains a low percentage of silicon, begins to granulate very soon after melting, unless a large amount of phosphorus is present.

The refining agent used in puddling is an oxide of iron, and a quantity of the latter is usually put into the furnace, in the shape of hammer cinder, squeezer cinder, or roll-scale, with each charge of iron. As soon as they are melted, the furnace is started to revolve slowly, the iron being covered by a bath of liquid oxide. To facilitate the operation, a small jet of water is now thrown, by means of a rubber hose, upon the descending side of the furnace lining, immediately above the liquid iron. This chills a part of the oxide, which, adhering to the lining, is carried down through the iron, oxidizing the silicon, phosphorus, and such other impurities as the iron may contain, and these become incorporated with the cinder. It is interesting to watch these changes taking place. The iron, which at first was quite fluid and somewhat resembling quicksilver, becomes gradually thicker, until, when the refining is complete, it has entirely lost its silvery appearance and comes to the consistency of thick paste or mortar, its melting temperature having materially increased. The bath of oxide, on the contrary, has become more fluid, and its melting temperature decreased. This operation is carried as far as possible without causing ebullition. The temperature is now raised so as to thoroughly liquefy all the oxide, which is now removed from the furnace through a tapping hole. When this is done, the furnace is again put in more rapid motion, so as to thoroughly agitate the iron. Up to this point, the iron has retained a large part of its carbon, which is now rapidly oxidized by the lining of the furnace and causes violent ebullition. The iron has now reached the granulated state, and occupies five or six times the space it did when fluid. The carbonic oxide gas, produced by a union of the oxygen of the lining and the carbon of the metal, presents a beautiful appearance as it bursts through the surface in many hundred jets of pale blue flame. When carbon is burned by free oxygen, it has no effect in reducing oxide of iron; but when the carbon is oxidized by the solid oxides of the furnace lining, the oxide containing it is reduced to the metallic state and is added to the charge; and as from 300 to 600 pounds of iron ore are used (in the shape of lining) for every ton of iron produced, it must be the iron reduced from this lining which increases the charge and makes it greater than the original weight of pig-iron. It is believed by many that silicon has this power to reduce oxide of iron to the metallic state; and it is a fact, well established, that iron containing a high percentage of silicon gives a better yield than iron containing but little silicon, although the carbon in both cases may be the same. The boiling operation usually lasts from ten to fifteen minutes, when the grains of iron unite, forming a spongy mass, which is then removed from the furnace to be squeezed, hammered, or rolled into bars, as may be required.

There were in 1870 and 1871 three forges built to puddle iron by this method—one each in Chattanooga, Indianapolis, and Pittsburg. In the two former, the furnaces and engines were poorly constructed, and, after working for about one year, the defects of building and abuse while working made the repairs so heavy that they were finally abandoned. The plant of ten furnaces in Pittsburg is still in successful operation.

In 1871, Mr. Danks visited England, and, by invitation, read a paper before the Iron and Steel Institute, at a meeting held in Dudley, giving a description of his furnace. This resulted in the selection of a commission of three gentlemen to visit Cincinnati and investigate the subject. The scientific part of the inquiry was intrusted to Mr. George J. Snelus (at that time in the employ of the Dowlais Works), the commercial aspect of the system to Mr. John A. Jones (iron-master of Middlesborough), and the practical working to Mr. John Lester (of Wolverhampton). They came over in October, 1871, bringing with them about forty tons of English pig-iron and iron ore, containing good, bad, and indifferent qualities, all of which were carefully marked. The lining was all taken out of one furnace and a lining of English material put in. Samples were taken from each brand of pig-iron for analysis; also, samples at different stages of the operation during puddling. They weighed all the material used and the iron produced. The examination was a very searching one, and the results fully accorded with our own previous experience. They visited Indianapolis and Chattanooga, where furnaces were at that time in successful operation.

In February, 1872, the first furnace on the Danks system in England was put in operation at the works of Messrs. Hopkins, Gilkes & Co., in Middlesborough. Specimens of the iron produced were severely tested, and exhibited at the quarterly meeting of the Iron Trade. The excitement ran high, and a public invitation was given for the Iron Trade to visit the works in a body on a certain day to see the furnace in operation. In the mean time, a written contract was entered into with the inventor to pay a certain price for the right to use two hundred furnaces; the contract was signed by Mr. Menelaus, on behalf of the manufacturers, and the day fixed for payment. But when the day came, it brought disappointment to the inventor; for, through the efforts of one or two members who had been unsuccessful workers upon this same problem, the contract was repudiated. Many members openly condemned this disgraceful proceeding, and four firms obtained licenses to build furnaces which would puddle 1000 pounds at a charge. Two of these firms met with the same fate as their predecessors at Indianapolis and Chattanooga, and from the same cause. I have no recent information as to whether the others are now working; but in 1878, Messrs. Hopkins, Gilkes & Co. produced with their six furnaces over 10,000 tons of machine-puddled iron, on all of which they realized a handsome advance in price over the iron puddled by hand, owing to its superior quality.

Soon after the starting of our first furnace in England, and the practical demonstration of the successful working of the machine, others entered the field, using our lining and cooling advantages without asking permission; among them were Mr. Adam Spencer, of West Hartlepool, and Mr. Crampton, of the Woolwich Arsenal. Mr. Spencer built an immense furnace, the cylinder of which was about ten feet long, and in which he worked one ton of iron at each charge. He met with the same trouble we had found in the long cylinder, and, failing to obtain a uniform result, soon abandoned it. Mr. Crampton made a new departure in trying to adapt pulverized fuel to the revolving furnace, in 1872. His furnace was a long cylinder with a water-jacket, the shell being made double, and a large stream of water circulating through it. The cylinder was divided into two compartments—one of which was intended as a combustion and the other as a puddling-chamber. The heat obtained is said to have been very intense, but the foreign matter in the fuel impaired the quality of the iron to such a degree that it had to be discontinued. Dr. C. W. Siemens has used the revolving furnace extensively for the manufacture of iron directly from the ore.

On March 5th, 1872, William Sellers, of Philadelphia, obtained patents for a revolving puddling-furnace, in which one end of the cylinder was entirely closed and the gases made to enter and leave through different flues at the open end. The closed end of the cylinder was provided with a large trunnion, by which its rotation was effected and also part of the weight carried, instead of a shiftable flue, by the removal of which access was had to the cylinder. The cylinder and engines were mounted on a pivoted frame, and could be turned at a right angle from their working position. I have no information as to the results obtained with this furnace, but believe none of them is now in operation.

The report of the English Commission made plain the fact that iron of an inferior quality could be rendered sufficiently pure by the process of mechanical puddling to be used in the open-hearth steel process, instead of the expensive charcoal bloom now used. Nothing of importance was done in that direction (in this country, at least) until about one year since, when the Otis Iron and Steel Company, of Cleveland, took up the matter under the direction of Mr. Samuel T. Wellman, superintendent of their works. Their scientific man and also a practical iron-worker were sent to Cincinnati, where our furnaces were at work. Samples were taken back for analysis, and, soon after, they purchased the right to build a furnace capable of puddling one ton at each charge. The cylinder of this furnace is built of steel plates strongly riveted together, and is six feet six inches in diameter and same length. The fire-grate is fitted with our automatic stoker. The furnace has been in operation about six months, and the product put into steel with such favorable results that others are now in process of erection.

It would require a large volume to record all the perplexing problems that have presented themselves to those engaged in perfecting this system. The point which perhaps gave most trouble was the abrasion ring at each end of the cylinder. These rings are not only subjected to a good deal of friction as the cylinder revolves, but also to unequal expansion and contraction. It was important that they should be kept cool; and if the workmen neglected to keep water turned on, they became hot, and, in cooling, became cracked, so that if a large stream of water was turned on, part of it ran into the furnace. The requirements of the case called for a ring which should stand the friction without wearing too fast, be of such material as would stand repeated heating and cooling; and constructed in such a manner that no matter how much water was turned on, it could not get into the furnace. About twenty-five different modifications were tried, both in wrought and cast-iron, and considerable time was required to test their respective merits.

The ends of the first cylinders were straight-faced instead of conical; and when the furnaces were cooled down on Saturdays, the lining was found to have a number of cracks varying from one eighth to three sixteenths of an inch in width, due to shrinkage. During the repairs to the brick-work, these cracks became filled with fine dust; and when the furnace was heated again, they could not close up, and the expansive force was sufficient to break the cylinder plates, though they were provided with heavy wrought-iron bolts and bands. This suggested the conical ends, which were found effectually to remedy the difficulty.

So, indeed, it might be said of nearly every detail of the present mechanical puddling-furnace—all have been suggested by experience; and, although many of the furnaces first started have been discontinued, the work of the past ten years has not been in vain; for progress, though

Digitized by Google

necessarily slow, has been sure; and it may be safely affirmed that the mechanical puddling-furnace of to-day is not only a durable but an economical machine.

The full benefits of mechanical puddling will not be realized until it has almost entirely abolished the present plan of making pig-iron for mill purposes. The fluid metal will be taken directly from the blast-furnace to the puddling-machines, where it may be worked in charges of one ton each; and the spongy ball, after having been squeezed into a compact bloom, say of fifteen inches diameter, taken directly from the squeezer to a powerful universal mill, and either reduced to a bar from ten to fifteen inches wide and one inch thick, or, if desired, made into a square billet of any size down to five or six inches; the bars cut and piled in lengths required for different purposes; the billets sheared and taken, while hot, to a heating-furnace, where, with a wash-heat, they may be rolled into any small sections required, without the intermediate process of piling, or having been allowed to cool, in one continuous process from the time the ore is first heated until it is bar iron ready for market. Working under such conditions as these, a product of ten or twelve tons can be relied upon from each machine every twelve hours (instead of one and a half tons made by hand) and of a quality superior to that produced by the old system.

THE SMELTING OF ARGENTIFEROUS LEAD IN THE FAR WEST.*

By O. H. Hahn.

(*Continued from page* 115.)

Retreatment of Speiss.—The question of reworking speisses for the silver and gold they contain has been left in abeyance as yet, although it is known that those produced in Eureka, Nevada, in the early stages of that camp, ran as high as $70 per ton in gold and silver. The speisses of Utah contain comparatively little silver and gold, but considerable cobalt and some nickel, also varying quantities of copper and lead. It is, however, more than doubtful whether it would be profitable to extract any of these metals. Speiss is, at all events, more difficult of treatment than matte. It requires grinding and bolting to separate metallic particles, and roasting at a very low temperature to prevent fusion. The process is, besides, very dangerous to the workman, as the dust produces painful sores wherever it settles on the skin.

Smelting-Furnaces.—The object of the smelting process, now to be described briefly, is to reduce the lead and silver contained in an ore to the metallic state, while the other metals remain in part combined with sulphur, arsenic, etc., and the remaining constituents of the ore unite with the earthy matter, forming slag. The smelting operation is performed entirely in blast-furnaces of different patterns and sizes, which should be adapted to the supply and grade of ore, character of fuel, cost of labor, and other local requirements. The cross-section of the shaft-furnaces of this country has varied from polygonal to circular and from square to rectangular, while the hight has remained almost the same for the treatment of easily reducible as for hard smelting ores, namely, from 12 to 14 feet above the level of the hearth-plates. Experience has proved that smelting in furnaces of small area can only pay in special cases, where, for instance, small supplies of rich ores, or refinery drosses, etc., are to be treated. For this reason, furnaces built on the Piltz principle of circular section are losing ground every day, while those of increasing rectangular section, like Rachette's, are rapidly replacing them. The diameter of a circular furnace can not be increased beyond four feet without evil consequences when working under blast of the customary pressure of half a pound per square inch. Blast of a higher pressure would require a corresponding increase in the hight of the furnace; otherwise, the furnace would become unduly hot at the throat, and cause great losses by volatilization. The capacity of rectangular furnaces, however, can be largely increased without raising the pressure of the blast by leaving the width stationary and merely increasing the length of the hearth area. There are furnaces running now successfully which have a section of 3 feet by 7 feet 10 inches, while the success of 54-inch "cupolas" is still to be announced. The smelting capacity of furnaces is, however, greatly modified by other conditions, namely:

1. The nature of the fuel used, whether charcoal or coke.
2. The volume and pressure of the blast.
3. The size of the material to be smelted.
4. The fusibility of the smelting mixture—to which may be added the temperature of the water, if water-jackets are used.

Charcoal of good quality will smelt more charges in the same time and under the same circumstances than coke; but coke will make cleaner slags and less flue-dust than charcoal. A mixture of charcoal and coke will be more advantageous economically in many localities than either alone. The size of the blower and the quantity of air it supplies should be adequate to the size of the furnace, else it can not reach its highest effect. In using blast of a low pressure, less material will pass through the furnace than with one of higher pressure; but it is advisable to work with a moderate blast, so as to allow the smelting mixture sufficient time for complete reduction. Hard ores require a blast of higher pressure than easily fusible ones. The formation of flue-dust can also be regulated by the pressure of the blast, aside from the fuel.

The best size of material for smelting is that of a goose-egg; iron and limestone flux, however, may reach the size of a man's fist, while quartz should be broken much smaller. Such material smelts very rapidly. Pulverulent ores give much trouble by sifting through the fuel and arriving before the tuyeres in a raw state, where they will cake together and form a sow, or enter the slag and cause a loss of metal. Very fine ores, such as slimes from concentrating-works, especially if they are rich in silver, should be agglutinated with milk of lime previously to putting them into the furnace; otherwise, a large proportion will be blown out of the furnace as flue-dust. If roasting precedes smelting, it may be found judicious to bind the roasted ore also with lime. If the slag should show undue quantities of precious metals, this would indicate the necessity of such a method.

The fusibility of an ore is greatly enhanced if it contains much lead and little silica, alumina, and above all no zinc compounds. A large percentage of oxide or silicate of zinc in an ore, even if properly fluxed, is liable to reduce the smelting capacity of a furnace to one half of what it would be if running on more favorable ores. This I have found to be a stern fact in my own experience.

These remarks will prove that, in the first place, a lead blast-furnace has no fixed smelting capacity in tons of material; and secondly, if we do rate its capacity, we should express it in tons of smelting mixture or charge, and not of ore.

The Modern Type of Furnace.—All smelting-furnaces are at present built with much more care, though probably at greater first cost, than the works of fourteen years ago, and with the view of saving every particle of metal that will leave a profit.

The hearth or crucible of the furnace is so strongly incased in cast-iron plates, and secured underneath by a bottom-plate, that the lead has very little chance to escape in that part. The interior is lined with fire-brick all around; the bottom is made of fire-brick also, in the shape of an inverted arch, so that any lead which might creep through the joints may not raise it up; and no tamping, to the composition of which old smelters paid so much attention, is used. The depth of the hearth is arbitrary within certain limits, say 22 and 30 inches. In one side of the hearth, close to the bottom, a channel four inches square (or round, if preferred), running up toward the top of the hearth-plates, is started for an automatic outflow of the lead. This may widen into a bowl at the top, to admit the introduction of ladles for dipping the metal, but not necessarily, as in many works the lead is tapped through an orifice a few inches below the upper edge of the hearth-plate into a cooling-kettle, so as to admit the skimming of the dross or impurities which may be suspended in the lead previous to its being cast into molds. The water-jackets are placed on top of the hearth-lining in such a manner that their interior lower edges are flush with the walls of the hearth. These jackets may be made of cast-iron, wrought-iron, or any other suitable metal, and may be set perpendicularly or inclined, or they may be provided with boshes of different angle (usually 65 degrees or 70 degrees) to suit the fancy of the smelter, and they may reach to the charge-floor, or may be only a few feet high. I prefer the jackets of Mr. Eilers's construction. They are 3 feet 6 inches high, and have a bosh beginning 10 inches above the center of the tuyere-openings, which are cast into the jackets. They are also provided with a large, projecting lip, rising four inches above the top of the otherwise closed jacket. This lip is open, and mainly serves for the purpose of keeping the jacket filled with water; but it also prevents the formation of steam, allows the introduction of tools to remove scale, and receives the feed-water. It is also provided with an outlet for the hot water. The cold water, on account of its greater density, sinks gradually to the bottom, while the heated water rises and flows into a waste-trough. This jacket, and in fact the whole furnace, has been adopted by many smelters with slight changes, but these changes are only of degree and not of kind. The tuyeres are 10 inches from the bottom of the jacket, and distributed symmetrically about the interior of the furnace, except in front—where they have been found inconvenient and even unnecessary—in the proportion of one tuyere of 3-inch opening for about every 2 square feet of hearth area. So a furnace of 3 feet by 6 feet 6 inches area would receive nine tuyere-openings; one of 3 feet by 5 feet, seven, and so on. The object of the boshes is to enlarge the horizontal section of the upper part of the furnace, with a view to diminish the velocity of the escaping furnace gases, and thus cool them. The front jacket—or jackets, if made in sections—is shorter than the others and reposes on 10 inches of brick-work, in the midst of which the slag-hole is located. This is done in order to facilitate the cleaning or "barring out" of the furnace by mechanical means, should it ever become necessary. Where the charge is of such a nature that the resulting slag will soften the brick front too much, a Luermann cinder-block can be inserted to advantage. The upper part of the furnace, including the chimney, rests on cast-iron plates supported by wrought-iron girders or rails, which are bolted at their ends to the top plates of four cast-iron posts. The space intervening between the tops of the water-jackets and these cast-iron plates, which may vary from one foot to two feet, and is left to facilitate the extraction of leaking jackets, is filled in with courses of fire-brick. The charge-doors are on the long sides of the furnace, not directly opposite each other, but each near diagonally opposite corners, in order to compel the feeders to spread their charges uniformly. The doors are high enough to allow a man to stand erect in them in case wall accretions have to be cut out; they are usually closed to within two feet from the bottom of the frame.

At a convenient hight above the charge-floor, a tube or flue, four feet in diameter, made of stout sheet-iron, is inserted in one of the walls of the chimney—which one, local circumstances will dictate—at an angle of not less than 45 degrees, terminating in a dust-chamber or a system of dust-chambers, which are again connected by a flue of sufficient size with a tall stack. The top of the chimney is provided with a door or damper, which can be opened or closed instantly by means of a chain reaching through the roof close to the feeder's grasp. In the flue connecting the furnace with the dust-chambers, frequently called the "downcast," there is also a damper, placed in such a manner that the feeder can at once open or shut off communication with the chambers. This arrangement is necessary to prevent explosions in the chambers through the sudden blazing up of the furnace, and to protect the workmen from the noxious fumes while the dust-chambers are cleaned out.

At the new Grant Smelting-Works, near Denver, the gases and fumes are drawn off below the level of the charge-door by a plan similar to the arrangement at Freiberg. For a full description of those works and drawings accompanying it, the reader is referred to the files of the ENGINEERING AND MINING JOURNAL, Vol. XXV., No. 12.

Water-Jackets.—Water-jackets have been adopted in every place where there is a sufficiency of water. But wherever the supply of water is scanty and unreliable, I should not advise their use, even if the material for lining the interior of the furnaces is not of unexceptionable quality. On this ground, I believe, the Eureka Consolidated Company has retained its ponderous stone furnaces; for the relining must be certainly expensive, if we consider that the sandstone has to be hauled a distance of thirty-five miles, and that mechanics there receive very high wages. It is true I saw, several years ago, a furnace in operation there which had been in continuous blast for more than a year, according to

* From advance-sheets of *The Mineral Resources of the United States*, published by the United States Geological Survey, Department of Industrial Statistics. Albert Williams, Jr., Chief of Department.

Digitized by Google

the statements of the foreman; but such campaigns are exceptional and are sometimes made for effect; probably it might have been wiser and better for the furnace if it had been blown out sooner.

Air-Jackets.—In May, 1878, the Eureka Consolidated Company had an experimental furnace erected by Mr. Gerrish, in which air-jackets were to take the place of water-jackets. These jackets consisted externally of sheet-iron, to which were bolted, by means of flanges, copper plates 1¼ inches thick, forming the interior of the furnace. There were eight tuyere-openings with four-inch mouths in the jackets, and one foot above the hearth. Eight inches above these there was another row of openings of the same diameter, but only in the outer shell, which were connected with the former by closely-fitting pipes. The object of these connections was to allow the hot air from the jackets to pass directly into the furnace. Each sectional jacket had of course a connection with the blast main. The furnace was elliptic in shape, and its hearth area corresponded nearly with that of the other furnaces, and was 3 by 6 feet. The blast was supplied by a No. 5 Baker blower, making 104 revolutions per minute. Unfortunately, the experimenter did not provide his furnace with a fore-hearth, as is customary in Eureka; and as he did not or could not flux the ore at all, he did not get the slag to run. A speiss sow frustrated the completion of his experiments. The impracticability of air-jackets was, however, proved to the satisfaction of the company and that of the numerous pilgrims who flocked to Eureka from White Pine, by the appearance of the copper plates, which were perforated like colanders by the action of the speiss.

Except at Eureka and a few other localities, all furnaces are now provided with closed breasts, and the slag is run out intermittently instead of continuously. The slag-pots are so constructed that they hold about 300 pounds, which corresponds to a charge of about 400 pounds.

Blowers.—The blowers mostly in use are the various sizes of the Baker patent, which have driven out of the field nearly all the Sturtevant fans and a good many Root's blowers. They give universal satisfaction, and do not require so much attention as the others. The blast is measured either by mercury or by water-gauges which are attached to the blast supply-pipe of each furnace. A column of two inches of mercury or of 28 inches of water is equal to the pressure of one pound to the square inch.

Fuel.—The fuel is either charcoal or coke, or both mixed. Too much stress can not be laid on the soundness of the wood from which charcoal is made. In Southern Arizona, and perhaps also in other regions, all attempts at smelting with charcoal alone have failed, and I found that all the oak timber, which was the most abundant for making charcoal, was rotten in the core. Hard charcoal from mahogany, cedar, etc., is also to be rejected for use in a blast-furnace, because it decrepitates into small particles, which have the same effect as coal slack or waste in chilling the slag through reduction of the temperature. Nut pine (piñon) makes the best charcoal, and this was formerly the principal fuel at Eureka. Charcoal from lighter woods, such as yellow and white pine, quaking aspen, etc., can not be used alone without reducing the temperature in a furnace. Every smelter who has practiced in Leadville will agree with me on that point.

The best coke I have used is an English patent coke, which is shipped extensively from Cardiff, Wales, to San Francisco, where it costs $14.50 per ton. It is porous and light, and leaves a very small percentage of ash. The Connellsville coke is the next best; it is very dense and heavy, and yields about 5 per cent ash; but it has been driven almost entirely out of the market in the West by the English and Colorado coke, on account of the freight charges, which swell its price to a high figure compared with the others. There are two kinds of Colorado coke in the market, the El Moro and the Crested Butte. I prefer the latter, others prefer the former; yet the difference is but trifling.

Owing to the different fusibility of different ores, the percentage amount of fuel must be referred to tons of charge, in comparing the consumption in various localities. This brings out the remarkable fact that smelting at a high altitude requires more fuel than at a lower one. In Leadville, for instance, the consumption of mixed fuel amounts to from 22 to 24 per cent of the weight of the smelting mixture, while in Salt Lake Valley it amounts to from 14 to 17 per cent; the lower figure corresponding to the summer and the higher to the winter season, when the ores absorb more moisture than in summer.

Where charcoal alone is used, the percentage of fuel is somewhat higher, probably between 26 and 28 per cent. Correct data are lacking, because this kind of fuel is usually thrown into the furnace by bulk, and the weight is only approximated. How little reliability can be placed on such approximations, I had occasion to experience in a remote mining district, where more fuel was used than the proprietor of the works had purchased (inclusive of waste). This is, of course, an absurdity. It is therefore advisable, in the interest of regularity of the furnace operations, to weigh not only ore and flux, but also the fuel, as accurately as possible.

Fluxes.—The fluxes most frequently used are:

1. Quartz, sandstone, clay slate, or other highly siliceous rocks, to supply any deficiency of silica which might be required to saturate the basic gangue in an ore.

2. Hematite, magnetite, limonite, and specular iron ore, and the various manganese ores, if iron is lacking in an ore.

3. Limestone, dolomite, and calcareous shale, if calcic oxide is not in sufficient quantity in an ore to form a slag of the type desired; to which may be added slag and metallic iron, it we follow Webster's definition of flux as "any substance or mixture used to promote the fusion of metals or minerals."

The action of slag is, however, more of a mechanical than of a chemical nature, unless it should have the characteristics pointed out in the discussion of slags. If a coarse-sized smelting mixture is to be worked, an addition of slag to promote its fusion is entirely superfluous, and would only increase the cost of smelting; but if the charge is very fine, or if much zinc is present in it, slag will very materially promote its fusibility. I have found the correctness of this statement to be confirmed while at Robinson, Colorado.

It is a matter of the greatest moment that the fluxes should be as free as possible from impurities, to insure success in smelting. So, a bituminous or a siliceous limestone would not be exactly the correct flux to select if we wanted lime for ore. As carbonic acid does not take any part in the composition of a slag, burnt lime would theoretically be the best; but as it rapidly attracts carbonic acid and water, thereby reducing its money value, and as it presents mechanical difficulties in the furnace, its application has never become general. It was at one time extensively used at the American Smelting-Works in Leadville.

An iron ore containing 22 per cent of silica and 68½ per cent of ferric oxide would be indeed a very bad flux, since the 22 per cent of silica requires a certain amount of ferrous oxide and also a certain amount of calcic oxide to form a slag of the same composition as is desired. The ferrous oxide required by the silica of the flux has then to be deducted from the ferrous oxide corresponding to 68½ per cent ferric oxide. The remainder will be the real available ferrous oxide (or "excess of iron," as it is termed in Leadville), which will probably not amount to one half of the original 68½ per cent. An admixture of iron pyrites in an iron ore would reduce its value in a similar manner, as so much metallic iron would have to be deducted from the total iron contents as is necessary to convert FeS_2 into FeS.

It does not require much reflection to perceive from the foregoing that the presence of extraneous minerals in quantity increases the bulk of the fluxes at an alarming rate, while the ore may become the smallest part of the smelting mixture. In this case, the percentage of lead in the charge will arrive at a point where smelting is no more profitable. Such cases have occurred in Southern Arizona, where bad fuel and poor fluxes have ruined the lead smelter.

(TO BE CONTINUED.)

FURNACE, MILL, AND FACTORY.

The Colorado Coal and Iron Company, at South Pueblo, Colo., is running on single turn, employing about 700 hands. It is quite busy, and was recently working on a large order of steel rails, 36 pounds to the yard, for the Chicago, Burlington & Quincy Railroad Company.

Captain William Hooper, of the Ticonderoga mines, reports that he has used Dixon graphite grease for coating wire rope, and, giving a coating once in ten days, finds that it prevents rusting and decreases abrasion.

A 150 horse-power Cummer engine will furnish the power for the electric light display at the Cincinnati Exhibition, and a 125 horse-power engine of the same make has been selected to drive a line of shafting at the Louisville Exhibition. The Arlington Woolen Mills, Lawrence, Mass., have put in a Cummer engine, and an engine has also been sent to the Nonatun Worsted Company, Newton, Mass. Among the recent orders are a 16 by 30 steam-jacketed condensing Cummer engine, by S. D. Warren & Co., Cumberland, Maine; a 300 horse-power engine for Messrs. Cain Brothers' flouring-mills, at Atchison, Kansas; a 90 horse-power engine for the Keokuk Plow Company, Keokuk, Iowa; an engine and boilers for the Case & Willard Thresher Company, Battle Creek, Mich.; and an engine for C. R. Cooley & Co., Hartford, Ind. At the 550 barrel flour-mills of D. Suppiger & Co., Highland, Ill., a Cummer engine was started a few days ago, and the Brush Electric Light Company, of Cleveland, has just put in a very large Cummer engine.

The new sheet and plate-mills at Birmingham, Ala., are completed.

The Talladega (Ala.) *Home* says that the Alabama Iron Company, at Alabama furnace, has increased its capital stock to $300,000, which is all paid up, and will shortly begin the erection of another furnace of a daily capacity of forty tons.

The Edgar Thomson Steel-Works, at Braddock, Pa., which are now blowing pig from the furnace directly, are putting in the Gjers soaking-pit.

Mr. W. Hollingsworth Whyte, one of the receivers of Thomas H. Paul & Son, says there are two or three parties in Baltimore who wish to buy the Paul Locomotive-Works, and that whichever of them becomes the purchaser will carry on the works. An order of sale at private sale was signed by the court recently. One of the probable purchasers is largely engaged in the machine business in Baltimore.

It is stated by the St. Ignace *Republican* that the Vulcan Furnace Company has 9000 tons of pig-iron on hand at Newberry. The entire amount will be shipped *via* the Detroit, Mackinac & Marquette Railroad and the Detroit & Cleveland Steam Navigation Company's boats to Detroit. The same paper mentions that the Martel furnace, at St. Ignace, has been doing excellent work since going into blast on the 1st inst. Three casts are now run off daily, and the charges are to be gradually increased until the maximum of production is reached. The iron produced is of superior grade.

The blast-furnace and the puddle-mill at Bay View, Milwaukee, were both shut down on the 20th. It is not known when either department will start up again. It is reported that the blast-furnace will not be started up again until next February, but this report is not accredited. An officer of the North Chicago Rolling-Mill Company states that, although it was not known exactly when the furnace will start up again, it would not remain idle very long. It is simply shut down to enable the company to work off the over-stock of pig-iron on hand at present.

The furnace of the Nova Scotia Steel-Works, at Trenton, was lit a few days ago, and the work of manufacturing steel has already begun. The works are conveniently situated on the banks of the East River, a short distance below Smelt Brook, between the river and the line of the Intercolonial Railroad. During the past year, the work of construction and collecting machinery has been in progress, and the establishment is now pretty well equipped. The Nova Scotia Company was formed on the 12th of April, 1882. The situation chosen is an admirable one; for, in addition to the proximity to the coal mines and the iron deposits of the East River, the facilities for shipment by rail or water are unsurpassed. A siding has been built connecting the factory and the coal-sheds with the Intercolonial Railroad, and a steam traveling-crane of ten tons capacity running through the main building moves all heavy weights from place to place when required. The buildings, which are suitable and substantial structures, cover nearly one and a half acres of ground, giving ample room for carrying on the work. The furnaces are capable of turning out some 9000 tons of steel per annum.

The creditors of Brown, Bonnell & Co. met at the bank of Wick Brothers & Co., Pittsburg. Among the more prominent of those present were Messrs. George A. Berry, of the Citizens' National Bank, and Solomon Schoyer, Jr., of Pittsburg; Daniel P. Ellis and W. H. H. Harris, of Cleveland; J. H. Van Dyke, Milwaukee; James Westerman, Joseph Firker, and B. Magoffin, Sharon; E. Ogleby, Wheeling; J. E. McFarland, Meadville; and W. H. Baldwin, J. H. McEwen, Paul Wick, F. H. Matthews, W. H. Baldwin, H. M. Garlick, John I. Williams, H. O. Bunnell, Ralph J. Wick, and A. B. Cornell, of Youngstown. Mr. George A. Berry, of Pittsburg, was elected chairman of the meeting, and W. H. Baldwin, of the First National Bank of Pittsburg, Secretary. Mr. Brown, the receiver, then submitted a detailed and complete report of the business done by the mills under his management. It was reported that a new company was forming. As a portion of the stock yet remained unsubscribed, Messrs. Paul Wick, James Westerman, H. O. Bonnell, Robert McCurdy, and William McCreery were appointed a committee to request the creditors who had not already subscribed to the new company to transfer the balance due them into stock. Before adjournment was had, a resolution was unanimously passed complimenting Mr. Brown on his management, and requesting the court to continue his receivership until the new company was ready to take hold.

From Jerome, Yavapai County, Arizona, Mr. Frederick F. Thomas, superin-

Digitized by Google

tendent of the United Verde Copper Company, reports to Messrs. Fraser & Chalmers, of Chicago, that the furnace and machinery furnished by them have worked very well, the furnace reducing 40 tons of ore and yielding 8 tons of black copper per day. The Silver Bear Copper Company, of Kansas City, has ordered a duplicate of the United Verde plant. The mine is near the Copper Queen at Bisbee.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY—TOMBSTONE DISTRICT.

GIRARD.—The Tombstone *Republican* reports that the mine and mill have been sold under execution, and bid in by Judge G. G. Berry for the amount of the execution and costs—$47,909.04. Under the new management, this property, which has been lying idle so long, will be started up.

PIMA COUNTY.

GUNSIGHT.—According to the Tombstone *Epitaph*, the sheriff has sold the entire property of this company to Charles Hudson, the banker, at the following prices: Mill, $40; Eastern lode, $41; Silver Girt, $40; Gunsight mill-site, $45; 160 acres, $40; total, $206.

PINAL COUNTY.

QUEEN CREEK.—The smelter started up recently is running on Australia ore. Every thing works well so far. The object of this run is principally to test the capacity of the furnace and the quality of the ore. A later report says that a heavy rain-fall has rendered it impossible to proceed with the work.

RAY COPPER COMPANY.—The superintendent reports to the New York office August 20th: During the last week, in Ray mine, winze No. 1 ran into a heavy seam of native copper, being the richest ore we have yet struck. We have sunk on the same some three feet. The north drift is still in the same character of ore as last week. These are the only two points I am working on, because the windlass can not do more than handle the ore as fast as we get it from these two places. I have been pushing the tunnel with all the force I could systematically work. I have also graded from the mouth of the tunnel to the dump, and fixed for the ore-dump. Winze No. 1 is now down 64 feet; the second drift is in 58 feet; north drift, 26 feet. The tunnel is cleaned out and retimbered 32 feet (about 85 feet to winze No. 1 through tunnel).

CALIFORNIA.

INYO COUNTY.

DEFIANCE.—During the past three months, the main incline shaft has been sunk 194 feet, making a present depth of 286 feet. The work is in a ledge carrying frequent bunches of pay ore. Two shifts are kept at work, and the shaft will be continued to a depth of 700 feet. The late run of the furnace was stopped until a supply of "wet" or lead ores can be extracted, with which to smelt about 100 tons of "dry," rich silver ores remaining on the dump.

PLUMAS COUNTY—GREENVILLE DISTRICT.

GREEN MOUNTAIN.—No. 6 tunnel is now in 1724 feet, and is advancing at the rate of seven feet per day by three eight-hour shifts. The company is just completing new cars, and will soon be running out rock, with a train of four. A horse will be put on as soon as the cars are completed, and it is expected an increased advance per day will then be made. The face of the drift is in favorable ground.

SAN BERNARDINO COUNTY.

BULLION.—Work was begun on this quartz mine about two months ago, and has been steadily prosecuted. Developments at the north end of the claim showed the ore to be very low grade, and hence work was suspended here and continued at the southeastern end of the claim. A shaft was sunk to a depth of 50 feet, which passed through a number of small pockets of very rich ore, but the average ore is low grade. While prospecting around the claim, a rich piece of chloride was discovered near the place where work was first begun at the northern end. Work will be temporarily suspended in the new shaft, for the purpose of developing the new strike.

KING.—Between the third and fourth levels, a rich strike has been made. A vein of ore about two and a half feet in width has been uncovered, and assays made show good results.

TAGGART.—Operations continue with good results.

SIERRA COUNTY.

ALASKA.—Two large boilers have been shipped to this mine at Pike City. About five car-loads of other machinery are now *en route*. The hoisting-works are to be rebuilt and in operation before winter comes. The burning of them a few months ago was a severe blow. The lower levels of the mine are showing up well.

RUBY.—The striking of gravel in a shaft that had been sunk from No. 2 tunnel has caused great excitement. Several car-loads of gravel have been washed, and have yielded five dollars in gold. The bottom of this shaft is on a level, and about one hundred feet ahead of the face of the lower tunnel. The lower tunnel will be pushed ahead into the new ground at once.

CANADA.

PROVINCE OF NOVA SCOTIA.

Reports state that the agents of a syndicate of Boston and New York capitalists has purchased the gold mine at Mount Uniacke, one at Chezzetcook, and, it is rumored, several others. Extensive works will be executed upon each of the several properties thus acquired, and the new proprietors intend to push things.

The Sydney & Louisburg Coal and Railroad Company has recently engaged in the manufacture of iron from the ore found in Cape Breton Island. The analysis of the ore as made by Mr. B. J. Harrington, lately Chemist and Mineralogist to the Geological Survey of Canada, is as follows:

Peroxide of iron	85·037
Phosphoric acid	0·032
Sulphuric acid	0·075

The ore is in large quantity on the Island, which also possesses an inexhaustible supply of coal, and the Cape Breton *Advocate* understands that it is the intention of the Reserve colliery to henceforth manufacture its pig-iron from native ores. It will, in that case, manufacture its own wheels and other iron work.

COLORADO.

BOULDER COUNTY.

VAN FLEET STAMP-MILL.—The mill now at Ballarat will be removed to Jamestown as soon as a proper site can be obtained. Good concentrating facilities are what Jimtown stands in need of.

CLEAR CREEK COUNTY.

PACIFIC MINING AND REDUCING COMPANY.—A dispatch from San Francisco says that this company has filed a petition in insolvency. The capital stock was $10,000,000. The company, it is said, expended $80,000 on its works at Idaho Springs, and also expended $80,000 here. The principal unsecured creditors are John Durand, of Rochester, N. Y., $27,644; Dwight Loomis, of Rockville, Conn., $12,296.95; and T. S. Dumont, Summit, N. J., $5337.93.

CUSTER COUNTY.

BULL-DOMINGO.—This mine, near Silver Cliff, which has been lying idle several years on account of litigation, is to be opened up again. The formation is very similar to the Bassick, and while the ore is not of so high a grade, the quantity is larger, as far as developed. All of the old lawsuits are either settled or dead, and the company has been reorganized, with a capital of $200,000. Out of this amount, a working capital of $65,000 is set aside for development-work. Mr. N. B. Stevens, the general manager and superintendent, is now on the ground, and will immediately put a large force of men to work. The concentrator, which has a capacity of from 75 to 100 tons per day, will be started up again. The mine formerly gave work to about 150 men.

HUMBOLDT.—On the 500-foot level, a rich strike has been made. The vein is twelve inches wide, and assays run high.

DOLORES COUNTY.

DOLORES VALLEY.—This organization owns 84 claims throughout the entire San Juan. In Rico, the company has buildings which cover eight town lots. The Zulu, Peru, Little Giant, Jenny Lind, Stony Point, Vampire, and Atlanta, all on Silver Creek, will be worked through a cross-cut tunnel which will cut the veins 1500 feet below the surface. From this tunnel, cross-cut drifts will follow each vein. The tunnel is in 190 feet through a very hard limestone formation.

EAGLE COUNTY.

BUCKEYE.—The Henry Dawson mine, the property of this company, has a shaft 174 feet deep, with numerous drifts, cross-cuts, etc., to say nothing of a cave of no small proportions, with ore exposed on all sides of it. There is in the main workings of this mine a breast of ore known to be forty feet in depth, from which numerous specimens showing free gold have been taken.

EL CAPITAN.—As soon as the best means for saving the gold are found, this property will be worked extensively.

WILD CAT.—This property is said to be one of the most valuable pieces this side of Tennessee Pass. It is developed by a shaft 175 feet deep and a drift in which they struck the ore, which has widened out and now covers the whole face. It runs in gold higher than any other property of this hill. The last find was gray quartz, in which the free gold was seen with the naked eye. It pans well, and assays show it to be a very valuable body, which in time will yield second to none in the camp. It has for some time been working under a lease, doing, however, development-work mostly, rather than with a view to the extraction of ore.

GILPIN COUNTY.

ILLINOIS.—A cross-cut to the north vein at a depth of 350 feet is driving. Since the formation of the pool, $29,000 have been expended in doing development-work in addition to what has been taken out of the mine.

WHITING.—A vein of mineral of over fifteen inches in width has been exposed. Sinking had been done alongside this vein. Another streak of pay—a brownish sort of iron—has been struck, which prospects well in the pan. The shaft is now down to a depth of nearly 300 feet, and sinking is continued.

GUNNISON COUNTY.

ROSE & REED MILLING COMPANY.—The company is ready to start up a five-stamp battery, which will be used to utilize the tailings, as it is believed that stamps will be more effectual in the work than rolls. There is room for twenty stamps, and more will be added when necessity demands.

SILENT FRIEND.—A seven-sixteenth interest in this mine at Pitkin, has been sold for $133,000. The remaining interest was recently purchased by J. W. Hanna, of Denver, in this mine. Both sales are made on a valuation of $300,000 for the whole mine.

WILDER-MCDONALD.—The concentrating-mill has commenced running. The machinery works satisfactorily.

LAKE COUNTY.

A new bank, to be known as the Carbonate Bank of Leadville, has been incorporated, to supply the vacancy created by the failure of the Bank of Leadville. It will open its doors September 2d, in the building occupied by the insolvent bank, with a capital of $50,000. Its incorporators include some of the best men of Leadville.

In our last issue, we referred to the California Gulch Extension of the Denver & Rio Grande Railroad. The latest information states that it will run up on the north side of the gulch, until the Rock and Stone mines of the Iron Silver group are reached. The road will then cross to the south side of the gulch, on the territory of the Gilt Edge chain, and, continuing up the gulch a short distance farther, will recross to the Breece Hill side, making a horse-shoe. The road will then again strike Iron Hill near the Colonel Sellers mine, and wind its way around the hill, ascending gradually, and passing on the way the mines of the Iron Hill Consolidated, Smuggler Consolidated, Silver Cord, and Iron Silver mines. The Rock, Stone, and La Plata mines will be placed within reach of the railroad by a siding which will pass the large Stone ore-bins. The enterprise of the Denver & Rio Grande Railroad Company will give the mines of California Gulch and Iron Hill a much cheaper and more reliable method of transportation for their products.

ADAMS.—Exploration-work in these properties on Carbonate Hill is making very encouraging headway. The drift from the Clontarf shaft, calculated to connect with the Brookland, has advanced 125 feet, which leaves about 175 feet of drifting to connect the two shafts. The drift is running in a solid body of ore, and the mine is shipping from fifteen to twenty tons of ore a day. The mineral in the bins at the mine is all a fine sand carbonate, running from forty to sixty per cent in lead and fairly well in silver. The entire product of the mine is said to be the result of development-work, and no stoping is carried on. The Brookland shaft is supplied with a new lift-pump, which has recently been ordered, and the pumping machinery on the shaft is idle in the mean time. The new pump will be in place and in working order within a week.

FANNY.—A strike of from four to six feet of galena and lead carbonates has been made. The ore, to all appearance, is not of very high grade, but the extent of the body will insure handsome profits for the lessees. The contact in which the ore was discovered is the same as that of the Nellie S. and other neighboring mines.

HARRISON REDUCTION-WORKS.—One of the four furnaces blew out August 20th, and it is expected that the others will be obliged to follow soon. Want of ore is the reason. It is hoped that the suspension will only be temporary. A report just received states that the company has succeeded in securing the ores of the Iron Hill Consolidation Company's mines. The output ranges from fifty to seventy-five tons a day; and the ore is said to be the most desirable smelting ore produced in Leadville.

IRON SILVER.—Included in the new work recently begun by this company is a large tunnel, driven in from the south side of Iron Hill, and calculated to pass below the large ore-bodies lately opened in the Lime and Bull's Eye claims, now working on leases and producing largely.

LEADVILLE GOLD AND SILVER MILL.—The stamp-mill has been shut down for some time past. It is not known when it will be started up.

LITTLE CHIEF.—A number of tons of the ore taken from the recent strike have been shipped to the smelters, and samples of the ore-breast return $150 per ton on the first-class material and $75 per ton on second class. The mineral is a galena and sand carbonate, and shows chloride of silver in appreciable quantity. The ore-body is situated 215 feet north of the Daly shaft, and about thirty feet west of the Little Pittsburgh line. The length of the Little Chief claim from the Daly shaft to the north end-line is 330 feet. The twenty odd jigs of this company, situated in Big Evans Gulch, have been closed down, throwing sixty-four men out of employment. Eight or ten men are still retained in sorting over ore containing a fair amount of silver and running high in iron. The jigs have been running for several months past, and added considerable to the production of the Little Chief mine during July. During the past few weeks, the grade of the dump material has deteriorated in value, until it was found impossible, by the closest work, to make the concentrating enterprise pay. By means of crushing and a complete concentrating mill, there is no question but that much

Digitized by Google

of the ore on the dump can be worked profitably, as well as the tailings from the hand-jigs that have lately been worked. Parties are experimenting, and have attained satisfactory results. The results are, that several offers have been made the company's manager for this material. No proposition will be accepted until the next annual meeting of the stockholders, in October next.

LITTLE PITTSBURG.—The drift from the No. 9 shaft, situated near the Amie line, has been extended northward along the line for 175 feet. Winzes and rises have been made at regular intervals, and in several instances iron ore, carrying small quantities of galena, has been intersected. In places, the iron has a thickness of sixty feet, tapering down to as little as two feet. Several tons of ore have been shipped, but only moderate returns were received. The Dives ground is being thoroughly exploited from No. 6 shaft, from which drifts extend to the O. K. and Little Chief claims. Should the work now in progress prove futile in the development of new ore-bodies, a drift will be driven from No. 9 to No. 10 shaft, as between these two shafts a strong chute of iron ore is known to pass.

O'DONOVAN ROSSA.—Operations are to be resumed.

SILVER CORD.—The hoisting-works, ore-houses, and other property of this company, destroyed by fire July 15th, are rebuilding in a more substantial manner, and it is expected that they will be running by the first of October. The mine is looking well, and has an output, with a temporary plant of about 100 tons of ore a day, which averages about $25 a ton. The total output for July was 2886⅓ tons. Expenses for month, $28,884.95. Profit, $40,524 20. This is a very good showing, considering the present circumstances. The total product from January 1st to August 1st, 1883, amounts to $703,332.97.

WILLIAM WALLACE.—The ore-streak, recently discovered and mentioned in last week's issue of the JOURNAL, has since opened out to about eighteen inches of fine mineral, and the ore-body continues improving as the work advances. The ore was evidently the southern edge of a true ore-chute, and gives indications of opening out into a large body.

PUEBLO COUNTY.

COLORADO SMELTING COMPANY.—The works have probably blown in by this time. The boilers were fired up on August 19th, and the main engine started for the first time. It worked smoothly. A big pile of ore is on hand, besides plenty of fuel. The ore-bins are nearly completed. The elevated tramway from the sampling-works to the smelter is ready for use. Only three furnaces will blow in at present, but the material is on the ground for the fourth furnace, and it can be built at any time on a few days' notice.

RIO GRANDE COUNTY.

SAN JUAN CONSOLIDATED.—Mr. Thomas M. Bowen has disposed of a controlling interest in this company to Mr. M. W. Cooper, of New York. The amount paid is reported to be $900,000. Mr. Cooper is very largely interested in the Annie Consolidated mines, which adjoin the San Juan. The mines are now to be worked very extensively.

DAKOTA.

CALEDONIA.—The superintendent reports for the week ended August 19th: Ore produced, 300-foot level, 945 tons; 400-foot level, 105 tons. Shipped, 473 ounces gold; value about $8000. The 400-foot level header has advanced five feet, making a total of thirty feet. All other parts of the mine look about as usual.

FATHER DE SMET.—The report for the week ended August 21st shows: Ore extracted from first level, 750 tons; second level, 750 tons; third level, 525 tons. Ore milled, 2025 tons. Golden Gate south header is in 20 feet.

FAIRVIEW.—Work continues. The main tuunel is in 200 feet, and will tap the ledge within the next forty feet, and 156 feet beneath the surface. The mill will be moved from Elk Creek to the Fairview.

ORO FINO.—Much of the machinery for the hoisting-works is on the ground, and will soon be in place.

IDAHO.

SOLACE.—This mine, which is owned by J. B. Haggin, of San Francisco, is showing a good vein of ore that, it is believed, will yield at least $500 per ton. The superintendent is endeavoring to make arrangements with the Vienna Mill Company to have a lot of ore now on the Solace dump run through the mill, but the rate, $35 per ton, is too high.

VIENNA.—The mill has been running steadily for six weeks. Of the 20 tons worked daily, about 12 tons are from the Mountain King and eight tons from the Vienna mine, both of which are the property of the company. The King ore is of low grade, while the Vienna ore is quite rich. The cost of mining and milling should not exceed $20. The ore-bodies in sight in the Mountain King and Vienna mines are very extensive, and ample to keep the mill running for at least three years. Specifications are preparing for ten additional stamps which are to be put in next spring.

MICHIGAN.

The following figures show the total amount of iron ore shipped from all lake ports up to August 22d:

	Tons.
Escanaba	821,929
Marquette	386,961
L'Anse	36,216
Total	1,245,106

NEVADA.

ELKO COUNTY—DELANO MINING DISTRICT.

This district was formed several years ago, and considerable work was done on the various ledges. Some of the claims paid for a short time, but there being no water near, and several other things operating against the district, it was abandoned for a time. Lately, however, work has been in progress on the Louisa mine, which has been developed to a depth of 110 feet on the ledge. The vein is five feet wide, having three feet of good ore, and two feet of ore mixed with clay. Assays run 30, 75, and 210 ounces of silver per ton. The shaft is to be sunk to a depth of 300 feet.

ESMERALDA COUNTY.

MOUNT CARY.—Work on the reduction-works is progressing rapidly. Timbers for the foundation are put in as fast as the grading is completed. The leaching-room is nearly finished. The greatest activity prevails around the works. One hundred and five men are employed on the grade, and every branch of the work is pushed with the utmost vigor.

HUMBOLDT COUNTY.

The copper mines recently located in what is called the Clove Meadows District are said to be quite extensive. Miners are now at work on one of the copper mines, which is now from 12 to 15 feet wide. It is the intention to take out about 1000 tons of ore before erecting smelting-works. This new district is a part of what is known as Columbia District, which embraces Bartlett Creek.

LANDER COUNTY—BORNICE DISTRICT.

The mill in this district is doing good work on ore from Goodell's mine. The roaster has not yet been started. The ore by free process works over 85 per cent. The first bar of bullion turned out was 989 fine.

LINCOLN COUNTY.

DAY.—It is the intention of the company not to start its furnace at Bristol for some time yet, but to make a long run when it is started. At the Day mine, sinking for another level has been resumed, and the shaft is now 35 feet below the bottom level. The ore-chamber on the lower level has been cut into at a depth of 30 feet, and it has been ascertained that the ore continues down to at least a depth of 50 feet, and how much farther work alone will show. Work is to be resumed on the Mendha mine at Highland.

STOREY COUNTY—COMSTOCK LODE.

The Leadville *Herald* states that some time ago a number of the most prominent mining and business men of Colorado organized a company, under the laws of California, for the purpose of prospecting for the southern extension of the Comstock vein. A tunnel was surveyed, calculated to intersect the vein at about 1600 feet from its mouth, and at about 900 feet below the outcrop. The tunnel is now in about 1500 feet, approaching the vein from the east side. So far, the work has all been in porphyry, with the exception of a few spurs of quartz, highly mineralized, and returning some very fair assays. The work is facilitated by the aid of machine drills, air-compressor, and other appliances, permitting rapid progress, and it is expected that the hanging-wall will soon be pierced, and the vein disclosed in all its strength and wealth. The enterprise is said to be one of the greatest in progress in the Sage Brush State, and, should it result favorably, will prove one of the greatest benefits to Nevada.

At Gold Hill, all mining operation are badly crippled on account of the low stage of water in the Carson River, which prevents the crushing of ore. This trouble will not end till the fall rains set in. Meantime about all that can be done in the mines is exploring and prospecting-work.

ALTA.—The report that some parties were making a determined effort to control the company for the coming year brought a large number of stockholders to the annual meeting held in San Francisco recently. The San Francisco *Exchange* says that fair play and no favor was the motto, and was carried out in spirit and letter. A resolution was passed by the company to allow all stockholders to redeem all stock bought in by the company for fifteen days after purchase of the same by the company. The following trustees were elected to serve for the ensuing year: W. H. Watson, W. F. Myers, W. H. Hoag, J. L. Armstrong, and S. de Greayer. The secretary's report shows:

Balance as per last annual report	$23,437.21
Receipts: Assessments Nos. 24, 25, and 26—25 cents each	80,996.68
	$104,433.89
Disbursements: Labor, supplies, tunnel drift (2362 feet), and all other expenses	60,063.83
Balance	$44,370.06

The balance is represented by various assets, including cash in treasury and on hand, $30,430.53.

NEW MEXICO.

BERNALILLO GOLD PLACER MINING ASSOCIATION.—The owners of the placer claim four miles north of Albuquerque have formed a stock company, to be known by the above name. The capital stock is placed at $250,000, and divided into shares of $250 each. It is proposed in this way to raise sufficient money to purchase machinery. The work of sinking the shaft on the placer is progressing.

COLUMBIA.—The Southwest *Sentinel* states that this mine at Lake Valley was sold to the Sierra Bella Company for $30,500. It is thought, however, the purchase was really for the Sierra Grande Company.

OLD MAN.—Workmen are engaged in placing a tramway in the incline shaft, and this, when completed, will give additional facilities and very materially increase the daily output of ore. Southwest from the shaft, a main or working tunnel has been started, and is said to be in ore already. At present, the company has 400 sacks of ore awaiting shipment, and on the dump there are upward of 1500 tons of milling ore, which will be reserved until such time as the company has completed its ten-stamp mill, now in contemplation.

RICHARDS.—This group of mines, consisting of seven claims, shows well for prospects, and some of the mines are producing ore of a smelting value, notably the Columbia. The shaft at fifty feet in depth exposes some fine ore. At this point, however, the crevice is not looking quite so well, owing to the intrusion of a horse, which promises to yield in a few feet. The Black Prince, at forty-five feet, presents a fine exposure of free-milling rock, estimated at two feet in width. On the dump are several tons of rock of fair milling grade. The Gladstone, belonging to the same group, and situated about three quarters of a mile distant from the Black Prince, is a wide vein of heavy iron ore showing spar.

UTAH.

COMET.—A car-load of ore from this mine, sent to Colorado for treatment, after paying the cost of hauling to Frisco, loading on cars, transportation to Colorado, commissions, etc., netted to the owners over $60 per ton For a single test of one car-load, this did well, and when the company gets its own reduction-works, it expec ts to get still better returns. It is putting in hoisting-works, which will soon be ready for operation. Drifts are running on the vein, cross-cutting is doing, and general development-work is going on satisfactorily. The prospects of the property improve as work progresses. This property was sold recently to a French syndicate.

BOX ELDER COUNTY.

FRISCO.—The ore continues to improve, and the vein grows larger and richer as depth is gained. There is a large quantity of high-grade ore on the dumps ready for shipment.

SALT LAKE COUNTY.

GERMANIA.—Two stacks are now running on Wood River ores, while a third stack is nearly completed for use. In connection with these works, the company has a sampling-mill, in which it proposes sampling the ores bought by it for reduction, as also for custom work. The refinery is getting into shape, and will soon be in operation on the silver-lead-bullion production of the furnaces. About 250 men will be employed at the first of November next.

SUMMIT COUNTY.

HOPEWELL CONSOLIDATION.—Investigation shows that, although upward of sixty thousand dollars have been expended, there is very little to show for it, and the property is still a mere prospect. It is now proposed to consolidate the Hopewell Consolidation, embracing ten locations, with a number of other properties, and form a combination which embraces twenty-six claims. If this scheme can be successfully consummated, it will include the Nettie B., Forrest, and a number of other valuable properties.

HORN-SILVER.—In this mine, on Horn-Silver Mountain, a large body of high-grade chloride mineral has been struck. The drift has been following a broken and uncertain stringer, which has just opened out into large dimensions. The pay-seam is nine feet thick. Six samples from the different layers in the face of the ore-body average 320 ounces to the ton.

MINNIE WHEELER.—A shaft is sinking to tap the vein. Cabins and other necessary buildings have been prepared, and it is the intention to continue work without interruption. The property lies close to the Crescent property, being separated only by the Union claim, and it lies in a square block 1400 feet wide and 1500 feet long.

VIRGINIA.

The discovery of tin ore near Lexington is reported.

HOUSTON.—About thirty tons of manganiferous iron ore are daily shipped to the Cambria Iron Company of Johnstown, Pa.

KENNEDY.—It is reported that a bed of manganese ore has been found on these iron lands, situated on the westward slope of Western Blue Ridge, Augusta County.

WAGNER.—J. B. White & Co. are sinking a new shaft on this land, about 30 feet from the shaft that was sunk five years ago, from which, at a depth of 26 feet, several hundred tons of good ore were taken.

MEETINGS.

Amie Consolidated Mining Company, No. 31 Broad street, New York City. Annual meeting of stockholders and election of trustees, September 15th.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, No. 49 Broadway, report that the petroleum market during the past week sold down to $1.05¾, gradually sagging from $1.08½, the opening last Friday, reacting to $1.08½, the opening to-day.

The principal reason for the weakness was that reports of development-work in the oil regions for August promised to be very bearish. The report that comes to hand to-day is less bearish than anticipated, hence the improved tone to the market. The report is as follows:

	Wells completed.	Wells drilling.	Rigs up and building.	New production.
July	260	262	232	3,800
August	309	315	261	4,267
August increase.	49	53	29	467

The high price of oil in June and July stimulated drilling of wells, and there are more wells now under way than for six months. With all these wells in view, and several of them important test-wells to the northeast of Balltown, it is unreasonable to expect any material advance. The charters for export have been large, but these must decline. For August there are 47,681 barrels, against 49,458 in May, 46,670 in June, and 39,634 in July. The "runs" up to the 28th inst. exceed the deliveries by 1300 barrels per day, but the accumulation of oil in August will be insignificant compared with the accumulation of 400,000 barrels in July. Refined oil is 7¾ against 7⅝ Wednesday. The petroleum market during the week has generally been dull, the short interest is not large, and the immediate fluctuations are likely to be within a narrow range.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Aug. 25	$1.07⅛	$1.07⅛	$1.06¼	$1.07	1,674,000
27	1.07⅛	1.07⅝	1.06¼	1.06⅜	1,842,000
28	1.06⅝	1.06⅞	1.05¾	1.05⅜	2,084,000
29	1.06⅛	1.07⅛	1.06⅛	1.07¼	1,682,000
30	1.07⅛	1.08¼	1.07⅛	1.07¾	2,112,000
31	1.08⅛	1.08⅝	1.07⅝	1.08⅝	2,264,000
Total sales.					11,658,000

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, August 30.

There is no improvement to note in the market for copper stocks, either in point of activity or prices. To say that the market is dull, feebly expresses the situation. There is, in fact, so little doing that it is almost impossible to get fair quotations, and the few sales recorded from day to day hardly give enough to form an opinion as to the future of business in this line of securities. Ingot copper holds its own very fairly, and, if it should advance from present prices, a change in the market for the principal producing mining stocks would surely follow. The situation is one of waiting and expectation. Calumet & Hecla sold early in the week at $240 and declined to $237, with sales again to-day at $240, and the stock is offered at that price; no bids. The whole amount sold was less than 25 shares, and shows how sensitive the market is. An order to buy 50 shares could not be filled without advancing the price several points; and the reverse, in case the order was to sell at best price. Quincy is steady at $45, all the sales being made at that figure. Less than 100 shares changed hands, and $44 is bid freely, without calling it out. Osceola declined from $18½ (August 14th) to $17¾, with later sales at $18, and closes $17½ bid, $18 asked. Allouez sold at $1¾, an advance of $¼ since last sale (August 14th). Franklin, Pewabic, and Huron are entirely neglected.

In silver stocks, there was a slight increase in the volume of sales at the regular Board over last week, confined, however, to two or three stocks, without any special change in prices. Sullivan sold as before at 87½c. At the Mining Board, sales are recorded at 95@77½c. Catalpa sold at 37½c., a decline of 2½c. Crescent is offered at 15c. without takers. We hear a rumor that Crescent is in debt to the Catalpa, and that the prospects of a dividend from the latter are not very promising. Bonanza declined to 1½c. Harshaw sold at 50c. as before. San Pedro, at 17c. Bowman Silver is slightly higher; sales at 18@19c. Massachusetts & New Mexico is dull at 4@5c. Silver Islet declined from $3⅛@$3.

3 P.M.—There was no change in the market at the afternoon Boards. Calumet & Hecla sold at $240, same as before. Pewabic, at $3¼ regular, and $3⅛ buyer 60 days. For Franklin, $9½ bid, $10 asked. Quincy, $44 bid. Atlantic, $10 bid. Osceola, $17½@$18. Silver Islet, $3 bid. Bonanza, $1½ bid. Bowman sold at 18c. Sullivan, 81¼c. bid; sales 85c., buyer 30. Dunkin, 28c. bid.

BULLION MARKET.

NEW YORK, Friday Evening, Aug. 31.

The market abroad has continued fairly steady the past week; but owing to large receipts here and declining sterling exchange, our market has been nominal and weak at the rates of accompanying table:

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Aug. 25	50⅝	110¼	Aug. 29	50⅝	110@110⅛
27	50⅝	110⅛	30	50⅝	110
28	50⅝	110⅛	31	50⅝	109⅞

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended August 31st, as compiled from various sources, amounted to $222,000, as against $214,000, reported for the previous week. The receipts from January 1st, 1883, to date are $7,613,974.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended August 25th	$581,605
Corresponding week last year	462,849
Since January 1st, 1883	8,913,129
Corresponding period last year	43,211,547

Imports.

Week ended August 25th	$1,380,941
Corresponding week last year	13,690
Since January 1st, 1883	9,602,774
Corresponding period last year	2,383,353

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £395,000 bullion, and the proportion of its reserve to its liabilities was raised from 46 11-16 to 49 9-16 per cent, against 39 3-16 per cent at this date last year. The bank made an additional gain of £75,000 bullion on balance. No report of the weekly statement of the Bank of France has been received.

METALS.

NEW YORK, Friday Evening, Aug. 31.

Copper.—Though quiet, the market exhibits considerable firmness, the only supplies of Lake copper available being from second hands. We note sales from of 250,000 to 300,000 pounds of Lake copper at 18⅛@18¼c. Many buyers indicate their willingness to take Lake at 15c., but there is little offering. Other kinds are naturally scarce, and the range remains 14⅛@14⅛c., according to brand.

A determined effort is apparently making to create the impression that almost under any circumstances the statistical position here warrants higher prices. There is no doubt that it is favorable, but the fact should not be forgotten that we are down to the world's market. We can not for any length of time maintain a much higher range of prices. A rise here, not accompanied by a corresponding rise abroad, could only be short-lived. It would simply divert into this market furnace material which now goes abroad, and the equilibrium would be quickly restored. If this quantity of copper which could thus be shifted were small and readily controlled, we might part company with the rest of the world. But it is heavy and would promptly force us down to the general level. This fact should be constantly borne in mind. No figuring can brush it aside.

The latest English cables are £63 15s. for Chili Bars and £69 for Best Selected.

Under date of August 17th, Messrs. Henry R. Merton & Co., of London, report:

American ingot copper has been sold at £63@£63 5s. net c. i. f. Liverpool for Orford, and £63 15s. for Baltimore. In Furnace stuff, the transactions have been 350 tons ordinary Rio Tinto Precipitate at 12s. 9d., 150 tons rich Rio Tinto Precipitate at 12s. 10½d., 450 tons Cape ore at 12s. 6d.; and at the Swansea Ticketing, 958 tons ores, averaging 9⅜ per cent, realized 11s. 3¾ d. per unit.

Tin.—Business has been quiet at 21c. for spot Straits. The arrivals during the month have aggregated 1700 tons, of which 300 tons are now on the dock.

London cables £93 12s. 6d.@£93 15s.

Lead.—Sales at the lower figures noted in our last having ceased, apparently because even they did not tempt buyers, and there being simultaneously a disposition on the part of Western holders to pick up cheap lead, the price has advanced to 4·30c., at which jobbing lots aggregating 300 tons have been placed. The firm attitude of holders makes it impossible to procure lead at a lower figure, and yet an effort to place large lots would promptly lead to a heavy falling off in the price. The situation seems to be largely artificial, a dead-lock, in which the sellers' side is at some disadvantage, because of the accumulation of stocks. Nothing is reported in Refined. In London soft Spanish has reached £12 7s. 6d.

From St. Louis, Messrs. John Wahl & Co. wire as follows:

The market remains the same, if any thing, a shade firmer. We note sales of 500 tons of Refined, September delivery, at 4·05c., and 130 tons of ordinary Missouri has been sold here to Eastern consumers at 4c.

Messrs. Everett & Post telegraph us to-day from Chicago as follows:

Buyers, fearing an advance, are coming forward and are buying lead quite liberally, so that there has been a large demand for spot lead during the past few days. Our market is strong and higher at 4·07½, 4·10, and 4·12½c.

Spelter.—The cheap lots by weaker producers are disappearing; and while there have been sales at 4⅜@4½c., it would probably be somewhat difficult to obtain supplies at the lower figure. England cables £15 for Silesian.

Antimony.—This metal is quiet, with nothing to report.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Aug. 31.

American Pig.—Business has been restricted to small lots, buyers pursuing strictly a hand-to-mouth policy. No. 1 Foundry continues firm at $21.50@$23 for standard and choice, while No. 2 is still in a less favorable position, showing occasional signs of weakness. We quote $19@$21, according to quality, while inferior to choice Gray Forge fetches from $18@$20, all at tide-water. In Bessemer pig, nothing new is reported and $21 full is now quoted. In Spiegeleisen every thing is quiet at $25.50@$25.75, while higher grades are dull at $30.50.

At the Exchange, the following transactions were recorded: Saturday, August 25th, 100 tons American Pig, No. 1, November, $21.87½; 300 tons American Pig, No. 1, November, $21.87½; 100 tons

Digitized by Google

American Pig, No. 1, December, $22; 200 tons American Pig, No. 1, December, $22; 100 tons American Pig, No. 1, January, $22.12½. Monday, 100 tons American Pig, No. 1, January, $22.25; 100 tons American Pig, No. 1, January, $22.25; 300 tons American Pig, No. 1, January, $22.25. Tuesday, 200 tons American Pig, No. 1, December, $22. Thursday, 200 tons American Pig, No. 1, November, $21⅞; 300 tons American Pig, No. 1, January, $22⅜. Friday, 200 tons American Pig, No. 1, December, $22.

Scotch Pig.—Business during the week has been dull at about our quotations. Arrivals are more moderate this week, and freights are cabled lower, 5s. from Glasgow.

We quote ex ship: Coltness, $23.75@$24; Langloan, $23.75@$24; Summerlee, $23; Dallmellington, $21@$21.50; Eglinton, $20.50@$21; and Glengarnock, $22.50@$23.

At the Exchange, the following slightly lower cable quotations were received: Coltness, 60s. 3d.; Langloan, 59s.; Summerlee, 56s. 6d.; Gartsherrie, 56s. 6d.; Glengarnock, at Ardrossan, 55s. 3d.; and Eglinton, at Ardrossan, 48s. 6d. Warrants to-day were 47s.

Rails.—The 40,000 tons Gowen-Vanderbilt are still in the market, not having been closed as yet. There are occasional small lots at recent quotations, but otherwise the market is very dull.

The low cables of English steel rails have given rise in some quarters to the fear that they might capture the Southern trade. Rails are now delivered along the Southern coast at $41, which is several dollars lower than the figures based upon English quotations.

Old Rails.—There have been sales of round lots at $22.75@$23, but it would be difficult to do better than $23.25@$23.50 now.

Scrap Iron.—There is nothing new to report.

Philadelphia. August 30.

The volume of iron transactions for the past week has been below the expected limits. Consumption is large, however, and stocks are generally of moderate proportions in buyers' hands. Low summer prices have led to but little heavy buying. The temper of the market is not favorable to large movements. The producing capacity is large and fully up to requirements; hence weak prices and cautious movements all along the line.

Pig-Iron.—Very little business was done. Small lots were bought, notwithstanding inferior iron was offered at very low prices. Some makes were offered at $17, furnace; but very little desirable iron can be had below $17.50, while $18.50 is firmly held for three or four of the brands that are mostly wanted. Good Forge happens to be fairly sold up, and buyers keep ordering ahead at about the same figures. Foundry brands are quoted $21@$23 for No. 1; $19@$20.50 for No. 2, with some business at an average of $20@$22. Both buyers and sellers are waiting for developments. There is very little room for any further decline, and producers are rather impatient at the dullness. They believe that, when some cause gives an upward turn to the market, consumers who are holding back for no good reason will rush in and place orders and perhaps lift prices 50 cents to where they ought to be.

Bessemer.—Scarcely any thing has been done in Bessemer, although buyers are ready to buy at their price. Prices have advanced to $21@$22 nominally, according to size of lot wanted; but best offers in a large way are under $21. Spiegeleisen has strengthened itself, but no sales can be reported. Quotations, $31.50@$32.

Blooms.—Small lots are inquired for at $48 for anthracite and $58 for charcoal. Sales of Muck Bars have been made in a small way at $34.

Merchant Bars.—But little has been done, and buyers are looking for a further decline. Iron has been bought as low down as 2·05c. Small lots of best makes 2·20c., but 2·15c. would command good iron. There seems to be no regular price. Manufacturers are anxious to get business, and in a good many cases have taken orders at about cost. Skelp is under fair inquiry, and two or three large orders will be placed in a few days.

Nails.—The production is likely to weaken prices. Stocks are not large, but with so great producing capacity prices are easily affected. Car-load lots are quoted at $3, and small lots are going as usual at $3.10@$3.15. Makers think the market will harden up again when September business comes along.

Plate and Tank Iron.—A good many small orders are coming in. The mills have a fair amount of business for September and October. Plate is ordered at 2·34@2·50c. Shell, 3@3·10c. Flange, 4@4·25c. Fire-Box, 5@5·50c.

Structural Iron.—The outlook at the opening of September is encouraging, both as to business on hand and as to inquiries. The railroads are doing a great deal of buying, and building requirements are up to the average. Prices are at their lowest possible limit. Angles, 2·40c. Tees, 3c. Beams and Channels, 3·50c.

Sheet-Iron.—Manufacturers have orders for September and October, and are all working full. For Common, 4@4½c. Galvanized is strong and steady at 45 off list.

Steel Rails.—Negotiations are still hanging fire at $37. Small lots, $38@$38.50.

Old Material.—Tees are offered for shipment at $23@$23.50. Double-heads, $25.50@$26. One small sale.

Scrap.—Selected Yard, $24@$25; No. 2, $23@$23.50; Cargo, $23@$23.50.

Pittsburg. August 30.

Neutral Forge is offered in 500-ton lots at $17@$18. Foundry iron is asked for in 50 to 100-ton lots, but prices named are not low enough. The market is weak, and sellers are now more urgent than buyers. Stocks seem to be accumulating, especially from outside sources. Bessemer iron is under fair inquiry, but no large sales have taken place, because of the high prices for shipment. Muck Bar is quoted at $34; Refined iron is weak at 1.90c., and even less in some cases. There is a strong probability of a shut-down of the nail factories, but some manufacturers think that the September demand will absorb the entire production and enable them to maintain full output at $2.90 rates. Steel rails are $38@$39. Old rails, $23@$24. Scrap iron of all kinds is dull and weak at unchanged prices.

Cleveland. August 30.

The market for the past week shows increased signs of stiffening, consumers taking larger lots and at holders' prices. There is a slightly increased activity in general foundry trade and a decidedly better feeling among mills. Soft foundry and silvery irons are scarce and in large demand, and good brands of strong foundry iron are not any too plentiful. With prospects of a good fall trade, we look for continued better condition of the iron trade. We quote:

No. 1 Bessemer	$21.50@$22.00
No. 1 Foundry, all ore	21.00@ 21.50
No. 1 Foundry, cinder mixture	20.00@ 21.00
No. 1 Soft foundry	21.00@ 22.00
No. 1 Open silvery	19.50@ 21.00
Mill irons	17.50@ 19.00
4 months. f. o.b. cars furnaces.	
Nos. 1 and 2 charcoal	24.00@ 25.00
Nos. 3, 4, 5, and 6 charcoal	25.00@ 27.00
Hanging rock charcoal	24.00@ 27.00
Strictly cold blast charcoal	30.00@ 33.00
4 months. f. o. b. cars Cleveland.	
Bessemer ores	6.50@ 7.50
Hematite ores	4.50@ 5.75

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Aug. 31.

Anthracite.

The circulars announcing an advance on different sizes of anthracite coal have gone forth into the world and have enjoyed their usual wide publicity. For years, there have been only one or two exceptional periods of short duration when the figures on paper have been actualy maintained, but in many instances an increase has had the effect of carrying values up to or near the circular issued a month previous. Judiciously handled announcements of this kind might have been made to produce that effect whenever the situation would warrant it; and it has certainly frequently acted as a stimulant. But, unfortunately, the temptation to use it as such in any case has been too much, and the companies find themselves in the ridiculous position of saying they want more money for their coal without having even a hope of getting it. The views expressed in our last issue have been sustained by the happenings of the past six days. We have not been able to discover that a single buyer has rushed into the market to cover what little requirements he had, and to-day coal is as abundant and is selling as cheaply as last week. The advance is entirely, so far as this market is concerned, a dead-letter. The chief anxiety of those who have coal to place—and there are few who have not—is to find somebody to take it, and no earnest effort is attempted to hold off for higher figures. Of course, those companies which, like the Reading, have a very heavy line trade, are comparatively well situated, as are those who secured a market months ago, by filling up to the best of their ability the best consumers in the market. But those who are naturally favored or have helped themselves do not admire the present state of affairs, which forces them to make concessions far beyond those which they expected to be called upon to make at this season of the year. With the opening of the winter, the market already contracts; and with an abundance of coal coming forward, the tide-water market will be glutted, especially at the present rate of production. The longer buyers wait, the better their position will get, unless the supply is curtailed by stoppage at the mines.

Until now the tonnage has been satisfactory; but it has evidently led to a heavy stocking of all available markets. The work of distribution should soon begin; but the labors of those who undertake this important function will be seriously interfered with if the present double and unreal position of the companies is not abandoned.

It is evident that the movements of the managers are now made exclusively for effect in financial circles. An air of exceptional prosperity is to be given to the interests involved, and to a certain extent this has been accomplished, but only at the expense of discounting the future. The legitimate trade, which has thus far borne the weight, is beginning to stagger under it seriously. Production and prices both can not be maintained.

Bituminous.

The trade drags along, with prices at low figures. In the Clearfield region, cars are getting a little scarcer.

Horsford's Acid Phosphate.

Beware of Imitations.

Imitations and counterfeits have again appeared. Be sure that the word "HORSFORD'S" is on the wrapper. None genuine without it.

WANTED.

An experienced and thoroughly competent chemist for a metallurgical works. One familiar with gold chlorination preferred.

State experience and salary expected.

Address "CANADA," P.O. Box 1833, New York.

PRENTICE & SON 24 B'WAY N.Y. EST'D 1842

Transits, Levels, Compasses, Rods, Chains, Tapes, Altitude Barometers, Air Meters, Drawing Instruments, etc.

In every variety of *superior* quality and at *de facto* reduced prices.

192-page Illustrated E. & M. J. Catalogue promptly forwarded.

AMERICAN PYRITES.

THE DAVIS COMPANY

IS NOW OFFERING

HIGHEST GRADE PYRITES.

ABSOLUTELY NO ARSENIC NOR ANTIMONY. NO ZINC NOR LEAD. LESS THAN 3 PER CENT OF SILICA.

An average of over seven thousand tons of ore consumed the past year gave over 48½ per cent of Sulphur, 45 per cent of which was recovered as sulphuric acid. It is the only pure granular ore ever found, consequently parts rapidly and easily with its sulphur, and requires less than half the usual furnace space. The mines are owned by the company, and are fully equipped for raising nine thousand tons of ore monthly. We have an unlimited quantity of both "Lump" and "Small" Ore. Contracts will be made for one or a term of years. Plans and full information for the erection of furnaces will be given free to users of our ore. Experienced burner men will also be furnished at ordinary wages.

Tide-water deliveries at Troy, N. Y.; Boston, Mass.; and New Haven, Conn. Address: THE DAVIS COMPANY, Charlemont, Mass., or P. W. COFFIN, Treasurer, No. 3 Merchants' Exchange, Boston, Mass.

THOSE who looked forward to another first-class mystery in connection with the explosion of the boiler of the Riverdale are doomed to disappointment. The boiler was simply excessively corroded, and could not stand the strain of more than ordinary pressure.

NOBEL'S gelatine dynamite is beginning to find its place in rock-blasting, and the indications are, that its principal field will be in the hardest ground, where its greater power fully comes into play, thus counterbalancing its increased cost. In softer ground, much of its power is wasted in shattering the rock, the quantity of material blasted out not being great enough to compensate for its higher cost ; and in some cases, where smalls are objectionable, being actually injurious.

THE completion of the Northern Pacific Railroad will, we are convinced, mark the beginning of an era of prosperity to the mining interests, notably of Montana. The industry which will be most directly and immediately benefited is copper mining and smelting in the Butte District. With increased outlets to market and better facilities for procuring fuel, the cost of production and of marketing ought to be materially reduced, and the Butte smelter be better than ever able to compete in the markets of the world.

THE Franklin Institute, of Philadelphia, has taken a step worthy of its past history and present high standing. It proposes to arrange for the holding of an international electric exhibition on the 3d of September, 1884. The great success of the Paris and Vienna exhibitions gives all the encouragement the enterprise deserves. Though probably visited by many Americans, and though closely watched by the American press, the two exhibitions referred to have not, it must be acknowledged, done much toward diffusing a knowledge of current progress among our own people. This, we feel sure, will be fully accomplished by our Philadelphia friends.

IN a well-meaning article on that hackneyed subject, "Is Mining a Legitimate Business?" the *Western Manufacturer*, of Chicago, with the object of illustrating a point, quotes a note on the Ray Copper Company, of Arizona, and then ventures the following rash opinion : "The probabilities are, that the whole territory of Arizona will not produce $5,000,000 worth of ingot copper in the next ten years." Let our Western friends take a slate and go to work with the following figures as a basis : Last year, Arizona mines produced seventeen millions of pounds of copper, worth, say, on an average, 16 cents per pound. This year, the insignificant mines of that poor territory will probably turn out not less than twenty millions of pounds, bringing in the New York market say fourteen cents per pound. Total, $5,520,000 estimated value. Had not the *Western Manufacturer* better multiply its figures by five, or, better still, abstain from writing on a subject with which it is not familiar?

A NOVEL method of sinking through ground carrying large bodies of water is now attempted at the Archibald mine, near Schneidlingen, Germany, by Herr H. POETSCH, of Aschersleben. He freezes the water. After sinking the shaft through 34 meters of dry ground, he struck the quicksand, and, beginning on the 9th of July with a temperature of the earth of 11 degrees Celsius, he had chilled the ground to 5 or 6·5 degrees below the freezing-point, the temperature of the strata in the center of the shaft being + 4 degrees. According to the latest accounts, working through the frozen material was to begin at an early date. It is possible that, under certain favorable conditions, such a process of preliminary freezing of the water-bearing ground may prove successful ; but we doubt its efficiency in any case where the water is under any pressure, small though it may be.

MR. J. S. JEANS, Secretary of the British Iron Trade Association, has issued a statement showing that, for the first half of 1883, the production of pig-iron in Great Britain was 4,138,225 tons, against 4,252,042 gross tons during the second half of 1882, and 4,241,245 tons during the first half of that year. This indicates a slight falling off, which is also noted in the stocks, which are stated to have been 1,315,775 tons on the 30th of June, against 1,368,854 tons in the beginning of the year. In many respects, this exhibit resembles that by which Mr. SWANK attempted to show that we are rapidly getting down to a sound basis. As with us, there is an evident movement in the right direction ; but its force is not great enough to carry the trade out of the lethargy into which it has fallen.

TECHNICAL TRAINING.

The most important contribution recently made to the discussion of technical education is the address of Dr. T. M. DROWN, delivered June 20th, 1883, before the Alumni Association of Lehigh University, by whom it has been printed in pamphlet form for distribution among those interested in the subject. This address is not only graceful and appropriate in form, but also full of felicitous observations—we might well say epigrams—which, like so many gleams of lightning, both strike to the heart of the subject and reveal with sudden illumination a comprehensive view of it. It contains a treatment of the question from the stand-point of a notably skillful and successful educator, who is himself, at the same time, equally distinguished as a practical expert and investigator. Dr. DROWN speaks with so much authority that his opinion would go far to settle the whole debate, but for the circumstance that his special point of view is that of analytical chemistry, both the science and the art of which occupy a peculiar position, not in all respects comparable with that of the engineering branches. That is to say, the "shop" of the analytical chemist is the laboratory ; and in the laboratory of instruction he can and does

Digitized by Google

perform the same operations as in the subsequent laboratory of practice. But Dr. DROWN'S familiarity with other branches of applied science is not inconsiderable; and moreover, his position as Secretary of the American Institute of Mining Engineers has given him special opportunity to watch the careers of school graduates as well as of self-educated, or wholly shop-educated, engineers. Perhaps nobody in the country could estimate fairly, in a general way, the professional standing and success of a larger number of engineers, chemists, and metallurgists.

Dr. DROWN takes strong ground in favor of distinct spheres for the technical school and the workshop. He does not believe in teaching the practice of an art in the school. His broad proposition is, that nothing should be taught in the schools which can be better taught in the field or the shop. Whether the practical should precede or follow the theoretical instruction, he does not positively say; but the drift of his argument shows pretty clearly that he thinks the student should go from the school to the shop or the field.

Not less earnest is his plea for separating the technical school from the curriculum of general culture. He would have the special teaching of engineering, chemistry, etc., be, like the special teaching of law or medicine, a distinct and a supplementary course. In this he is quite right. Some parents may be obliged by poverty to omit the bestowal of a liberal education upon their sons, and to thrust them at once into the immediate preparation for bread-winning. We would not reproach such victims of necessity. But it should be clearly understood that such defective education is an evil; and when they who take this road presume to praise it as the best, they intensify the evil into a nuisance.

Dr. DROWN offers also a timely criticism upon the cramming process which threatens to swamp our technical schools, and by which the aspirant to a degree is made nominally proficient in a dozen different branches, all of which are indeed pertinent and useful, but can not be mastered by one mind in one course of three or four years, now that each branch has been, in the swift progress of this generation, developed into a science by itself. As he justly remarks, "We must be reconciled to the necessity of becoming specialists, and of calling in other specialists to help us. Perhaps the most we can hope for is to be an expert in one department, and to know enough of the related departments to judge of the harmony and fitness of the combined work of many heads and hands."

It is this irresistible tendency toward specialization which makes the scientific and technical courses of the present day such poor substitutes for the full, liberal course, so far as the general culture of the mind is concerned. They do not widen the sympathies and extend the associations. Their natural effect is rather to narrow and intensify the mental activities. If a man is not to become a specialist and nothing more, he must have received, before entering upon his professional training, a culture which will have developed and strengthened tastes and powers capable of resisting the influence of the technical school.

Dr. DROWN'S description of that function of the school which puts the student "into synchronous motion with the science he is studying," is peculiarly happy. But it evidently applies to the analytical chemist pre-eminently; to the physical tests of materials in a smaller degree; and to general engineering scarcely at all. His idea is, that the technical school should be the center of original investigation and experiment; and that this is one of the best possible elements of instruction. This is true enough in chemistry and physics. It has been successfully proved by GIBBS, DROWN himself, and other notable teachers of chemistry; and that part of the address before us which dwells upon it is an interesting revelation of the methods of a famous educator. *

A NEW BRANCH OF ENGINEERING.

A need of which the American public in general, and many individuals and corporations in particular, have been for some time keenly yet vaguely aware, is the service of men capable of giving expert advice on all matters connected with the management of forests. On all sides, we hear that something must be done with regard to the timber supply and the waning forests of the country. Congresses are held; associations are formed; and innumerable "cranks" ventilate their theories and plans. Meanwhile, in certain localities and for certain industries, timber grows steadily scarcer and dearer; and land-owners, with the best will in the world, seeing that they can not afford systematic forest planting and culture after elaborate foreign methods, and not knowing what else they can do, do nothing. Those who simply resolve not to cut down their forests are perhaps the most foolish of all; for there is a stage of growth at which forests should be cut down. And those who, after cutting, do nothing more, but leave the future to nature, find that nature presents them with worthless "scrub" material, instead of the valuable trees they have removed. Now, the all-important fact is, that without large expenditures, and without complicated administration after foreign models, a great deal can be done under present conditions with certain profit. But experienced foresters only can decide, when and what and how. Under the advice of such men, unskilled proprietors and laborers of merely ordinary intelligence and fidelity can accomplish much in the redemption and preservation of valuable timber-species.

In many parts of the East, notably in the anthracite regions of Pennsylvania, the question of mining-timber is a pressing one. The forests which have furnished it hitherto, many thousand acres of which are owned by the great anthracite companies, do not spontaneously renew themselves in satisfactory quality; and the lands themselves, after the forests have been cut, relapse into a worthless wilderness. In many such cases, the owners would no doubt willingly try to remedy this evil, if they could begin tentatively, and on a modest scale. It is not surprising that they are disinclined to launch at once into a grand experiment, and surrender themselves to the theories of enthusiastic naturalists or speculators. We are inclined to believe that, in the vast majority of cases, eleborate schemes of forestry will not pay. The time is coming, but it has not yet come, when slow-growing hard-wood forests can be planted and cultivated, so as to pay fair interest on the investment. There are, no doubt, localities where even this can be done with advantage; but a large part of the work of an expert adviser would probably consist in demonstrating to parties entertaining such schemes the premature character of that sort of work at present. On the other hand, the numerous things that could be, and ought to be, and are not, done by forest-owners, the doing of which would bear fruit at once in increased profits or increased reserves, or diminished waste and favorable renewal of timber-species, would furnish a field for practical advice of great immediate value.

Whoever undertakes to give such advice should be a thoroughly trained forester, familiar with what has been accomplished abroad, and also with what can be done here. Above all, he should understand our commercial conditions, and not be tempted to recommend what is not practicable on that side as well as on the side of technical arboriculture. We are glad to notice that this branch of engineering is now beginning to be represented in this country, and that, as an evidence of this new departure, an office has been opened in this city by Mr. BERNHARD E. FERNOW, whose contributions to various technical societies and to the *Charcoal Iron-Workers' Journal* and other journals have attracted general attention. His career as an official in the Prussian forestry service, and his residence of many years in the United States, where he has managed forest-lands, supply the requisites needed to qualify him as a prudent and safe adviser. The American Forestry Congress recently re-elected Mr. FERNOW as Corresponding Secretary; and in this capacity he is well known in the United States and Canada to the leading authorities in that line. The work of a few engineers with a thorough theoretical and business training will do more to meet existing evils and to organize a reform than endless discussion by amateurs, and for this reason we heartily welcome the pioneers of a new branch of engineering. *

A METHOD OF DISTRIBUTING WEATHER FORECASTS BY MEANS OF RAILROADS.

In a paper read before the American Association for the Advancement of Science, Mr. T. C. Mendenhall describes a system that has only been in operation in Ohio for about a year. To distribute forecasts, signals are placed upon the sides of the baggage-cars, as distinct as possible from each other, so as to be easily recognized at considerable distances, and also to convey as much meaning as possible, so as to predict as many different conditions. A combination of form and color was adopted. The signals are three in number as to form and two in number as to color. The red signals are confined to predictions as to temperature—rise in temperature, stationary temperature, falling temperature. The other color is blue, and that is confined to predictions in regard to the general state of the weather. The question of form was a good deal considered, and three forms were adopted. The sun, moon, and a star were chosen, because every body is familiar with those words. Experiments were made with the triangle, and finally rejected. The device for attaching to the car is due to Mr. Anderson, who has been in the service of the board of commissioners for the past year; and it is really a happy device. The signal is made as large as possible, and the disk can be seen at a long distance. The red sun and blue moon mean higher temperature and general rain. The crescent means lower temperature. The full disk of blue means general rain. The star represents local rains. With regard to the proper working of the system, though it has been in operation but a short time, it has really done good work. Special telegrams are received every morning, and they are transmitted to the train-dispatchers at five o'clock. As yet it is operated only on one railroad. It happens, fortunately, that that road goes through an agricultural region of considerable importance, connecting the cities of Columbus and Cleveland. Two trains start out in the morning at the middle point between those cities. The signals are put on the cars at five o'clock in the morning; and as they run through the morning hours, the farmers along the line can have an opportunity of seeing them and predicting the weather for the day. The railroad company circulated through the whole line little cards having these signals displayed in colors, with their meaning in every combination. This helps, because it enables every body to understand what is meant. A recent communication from General Hazen indicates a disposition on the part of the general government to take hold of the matter and bring it into general operation as far as possible. Postal cards have been sent to various persons along the line, with questions in regard to the practical working of the system, which are answered and sent in at the end of every week; and it has been found that on the average eighty per cent of the predictions are verified.

The Sulphur Compounds in Gas-Lime.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: While occasionally experimenting with gas-lime (from the purifiers of the Philadelphia gas-works), I have found that it is not constituted as I think is generally believed; and therefore it may be of interest to give the results of an analysis of it. The combinations to which I call attention are those of sulphur and also of cyanogen with lime. The latter, however, are present in very small quantities only; the combinations of sulphur form the greater part of the gas-lime. I will explain here, in what form and combination the sulphur and cyanogen are contained in the gas-lime, and how I came during my investigation to these conclusions.

I found sulphur, not, as I first expected, as sulphide, but in its free state, and especially as hyposulphite; and I found that the cyanogen combination is a sulpho-cyanide. The latter was found in small quantities in the solution, by treating the lime with cold water, filtering, and extracting with alcohol. The cold aqueous solution did not give the least reaction for sulphureted hydrogen, as it would do, to some extent, if sulphide of calcium were contained in the lime. It reacted for hyposulphurous acid, and was of alkaline nature.

I then boiled some gas-lime with water, and filtered. The solution had a yellow color and reacted for sulphurous acid and also for sulphureted hydrogen. There was no doubt that the hot aqueous solution now contained some sulphide of calcium and sulphite of lime; but the following tests prove that these were not contained in the gas-lime in the same forms before it was boiled, and show how they came to be found in the hot aqueous solution.

I took a quantity of the gas-lime, and boiled it with water and carbonate of soda, the latter a little in excess of the lime. By this treatment, the combinations of lime with sulphur, as sulphide (if such be present) and the hyposulphite, will be converted into carbonate of lime and sulphide and hyposulphite of sodium. If sulphide of sodium be present, the solution should give, after filtering, the reaction for sulphureted hydrogen; but this it did not do; which showed conclusively the absence of sulphide of sodium in the solution, and consequently the absence of sulphide of calcium in the lime: the solution contained hyposulphite of soda. To assure myself of this, I made counter-experiments with sulphide of calcium and carbonate of soda, which gave the reaction for sulphureted hydrogen in the filtrate, as also sulphide of calcium treated with cold water gives a plain reaction for the same. But how could the lime show the reaction for sulphureted hydrogen, thereby proving the presence of sulphide, after having been *boiled* with water only? This is explained by the following facts: Hyposulphite of lime is, when boiled, converted into sulphite and free sulphur; the gas-lime itself contains free sulphur and some caustic lime, and these, when boiled, are partially converted into sulphide of calcium, having the formula CaS_5. In the presence of carbonate of soda, the action of sulphur on the lime and the formation of this sulphide is excluded, and the sulphur is kept in its free state, while carbonate of lime is formed; and hyposulphite of lime is converted into hyposulphite of soda and carbonate of lime.

In the quantatitive analysis of the gas-lime, it is necessary to determine water, free sulphur, insoluble matter, alumina (and iron), silica, sulphocyanide of lime, hyposulphite of lime, carbonate and caustic lime. Free sulphur is extracted with bisulphide of carbon. A portion of the lime being treated with alcohol, the evaporated filtrate will show the amount of sulpho-cyanide of lime. The lime is brought into solution by hydrochloric acid; some insoluble matter is left; the solution contains all the lime, alumina (and iron), and silica, all of which can be determined by weight. To determine the hyposulphurous acid, the gas-lime must be boiled with water and carbonate of soda, filtered, and the hyposulphurous acid determined in the solution volumetrically with iodine. Carbonic acid will be found by adding to the gas-lime a solution of chromate of potash, and then gradually nitric acid, until all carbonic acid is driven out: the difference in aggregate weight of the apparatus, lime-solution, chromate of potash, and nitric acid, before and after the evolution of carbonic acid, is the amount of the latter. The difference between the whole lime and that combined with hyposulphurous and carbonic acid is the amount of caustic lime.

The result of the analysis was the following:

Water	9·793
Insoluble matter	3·562
Sulphur (free)	3·782
Alumina (and iron)	4·401
Silica	3·559
Hyposulphite of lime	49·343
Carbonate of lime	21·260
Caustic lime	2·417
Sulpho-cyanide of lime	2·150
	100·267

PHILADELPHIA, Aug. 28. ADOLF GLEIM.

Belt Copper Mines, Limited.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: We are not, as a rule, in the habit of noticing anonymous communications; but we trust you will allow us, on this occasion, to reply to a communication signed "Specular," referring to the above mines, which appeared in your issue of the 28th of July last. We are unaware of the object which has prompted this and other similar communications which have recently appeared in various local American periodicals; and we are anxious, as the consulting engineers to the company, and those, therefore, primarily responsible, to correct various inaccuracies in it, the chief of which is an insinuation that the present stockholders were induced to invest in the undertaking under what, it is implied, were virtually misrepresentations.

Although the spirit of the communication would lead a casual reader to infer that the writer was intimately acquainted with the property, it is easy to deduce that the information embodied in it has been obtained second-hand.

We are content to pass over the philanthropic spirit by which your correspondent professes to be animated, and even to thank him for the compassion which he is good enough to express for the misguided British investors who have been beguiled into so unpromising a venture; but, in justice both to the original vendors and to ourselves, we must energetically protest against the insinuation conveyed in his letter, that the present stockholders were induced to invest in the enterprise under false representations, which, according to his letter, could only have emanated from American sources.

It is only fair to the mining element of the peninsula to point out that no American experts were employed on behalf of the company to report upon the property, and that it was simply and purely acquired on the recommendation of English mining engineers, after an exhaustive examination made by our firm, in conjunction with one of the best-known mining experts on this side of the Atlantic; so that, whatever the future of the mine may be, we, together with the gentleman just referred to, and we only, are responsible for its acquisition by British capitalists.

In order to protect themselves so far as possible, the directors of the company, previous to taking over the property, applied to the Royal School of Mines in this city to nominate a responsible firm of engineers; and we had the honor of being named by that institution to examine into the resources of the mine and check the reports made by the American experts. Our examination proved satisfactory, and the capital was subscribed chiefly from private sources.

The stockholders knew from the first that the property was almost a virgin one, and that the amount of work done was relatively insignificant; but they were satisfied with our opinion that the veins, where opened up, were strong, persistent, well-defined, and fairly productive, and that, given the necessary time and money, there was no reason why the mine should not develop into as good a property as any of those lying around the shores of Portage Lake. To this opinion, confirmed by a recent and exhaustive examination of the mines, we still adhere.

During the visits referred to, we discussed the possible future of the Belt mines with many of the oldest and most experienced miners of both the Houghton and Ontonagon districts, and the unanimous opinion of those best qualified to judge was, that no reason existed to prevent the Belt mines from proving as productive as their great rivals on the more easterly portion of the peninsula.

It was generally admitted that, while most of the great mines in the Houghton District had enjoyed the numerous advantages derivable from a sufficiency of funds, those in Ontonagon County had been started in the majority of instances with insufficient capital, and compelled to draw their financial supplies from the mines themselves, which, never having been sufficiently developed, finally collapsed from pure inanition, due to want of capital.

We may call your attention to the patent fact, that the principal fault your correspondent finds with the mines is, that they were badly worked and managed in former times; a state of things which it will be little to our credit if we can not reform. The comparison between the daily output of a mine like the Quincy and that of a property on which no work has been done for a long series of years does not call for further notice.

Respecting the points to which a practical miner would attach importance, there is hardly a reference in your correspondent's letter. A brief remark that some person or persons unknown considered the ore was too lightly charged to pay for working, virtually covers the whole question of mining and production.

We may point out that the plant of hoisting and compressed-air machinery for which he intimates "preparations are making," has been at work since February last; that a drift was commenced from a shaft on the Knowlton vein long prior to the present company resuming operations; and that the depth of the shaft on the Bohemian was 180 feet, instead of less than 60 feet, as asserted by him.

The closing remarks of your correspondent are condemnatory of the enormous outlay of capital which is taking place, a criticism somewhat difficult to reconcile with his prediction, in the preceding paragraph, that, at the present rate of development, it is hopeless to expect any thing at all from this property for two years to come. We trust soon to be in a position to offer a practical refutation to this remark.

In conclusion, we again protest against the effort of your correspondent to sow the seeds of discord between the mining interests of two sister nations. Whatever the final result may be, we are content, as we have said, to accept a responsibility which we gladly welcomed from the first.

With a sufficiency of capital to enable us to tide over even a prolonged period of development, an able and industrious staff, and with, as we believe, as good a mine in prospect as any on the peninsula, we await the issue with every confidence in its ultimate success. We are, sir, your obedient servants, BAINBRIDGE, SEYMOUR & RATHBONE.

WESTMINSTER, 2 GREAT GEORGE STREET, Aug. 21, 1883.

THE WAYS THAT ARE QUEER OF JAPANESE MINERS.—Japanese miners have some curious customs which sadly depreciate the value of their work. They do not appear to appreciate the fact that "time is money." An engineer who has just returned from the mines of that country tells us that they light them in a peculiar manner. Every man entering the mine carries with him a large bundle of from five to six-foot bamboo cane, slightly beaten before use. This cane is used as a torch. It burns fairly well for a few seconds until a notch is reached, when the light nearly goes out and the ashes must be knocked off, a process which must be repeated every half-minute. Every six or seven minutes, a new cane must be lighted, so that a good share of the miner's time is occupied in keeping his illumination in a fairly satisfactory condition. Unfortunately, Japanese miners are, besides, great smokers, and they use a pipe having a bowl the capacity of which is equal to that of an ordinary thimble. It takes two whiffs to finish it, when the process of filling up and lighting it must be gone through. Every one has probably had occasion to watch the great deliberation with which an average Irishman, when at work, will fill his clay bowl when the foreman's gaze is not on him; but imagination simply shrinks from the task of picturing the rapid progress of work intrusted to a smoking Japanese miner.

NOTES ON THE EXHIBITION AT DENVER.—II.

Special Correspondence of the Engineering and Mining Journal.

THE BOULDER COUNTY EXHIBIT.

The exhibits in this section represent about two hundred mines, and the richness of the display stands unrivaled in the Exhibition. There are numerous specimens showing solid pieces of gold as large as a five-dollar piece, and nuggets of pure native silver weighing pounds, besides a fine collection of specimens of that ore second only to native gold, namely, telluride of gold. In the cases are shown the finer picked specimens of ore from the various mines; while in another compartment there are large blocks of ordinary ores, to indicate that the mines are good producers of quantity as well as quality.

The Grand Island District has a very rich show in the cases, in which the following mines take part: Caribou, Poor Man, Seven-Thirty, and St. La Sare. These mines exhibit native silver as wire and nugget, pure silver-glance, and beautifully crystallized brittle silver (stephanite), also ruby silver, rich galena, gray copper ore and arsenite, and nearly all the silver-bearing copper and lead ores. The next case is occupied by high-grade telluride and free gold ores from the Sugar Loaf, Gold Hill, and Central districts. The principal mines represented are the Slide, Prussian, Smuggler, Richmond, Malvina, New Enterprise, Keystone, Mountain Lion, Grand View, and others. There are free gold ores from the Richmond and the Smuggler worth $120 and $70 per pound respectively. A case full of tellurides from the New Enterprise mine is shown which run from $50 to $70 per pound. Another lot of ore, high-grade galena, comes from the Roman Eagle mine, Jamestown. The Black Cloud, in the same district, exhibits some medium pay ore in good-sized blocks, consisting of sulphurets of copper, lead, and zinc, containing $120 per ton of silver and gold. The Buck Horn, which is celebrated as the first mine that started the so-called Jimtown rush, shows some blocks of $70 silver ore with 50 per cent lead as galena.

The Ward District, embracing the Columbia, Celestial, Morning Star, Baxter, and Ny Wot mines, shows some blocks of gold-bearing pyrites. Some fine specimens of copper pyrites are exhibited by a mine in Pennsylvania Gulch, containing $180 silver and 37 per cent of copper. Among the large blocks not in the cases are some splendid lumps of galena from Caribou, assaying from 300 to 500 ounces of silver per ton; also, similar pieces from Poor Man and Black Cloud. There is a quantity of a very fine magnetite ore, also from Caribou mine, which contains a vein of it no less than 40 feet thick. A splendid and curious specimen of galena intermixed with pink fluor-spar is shown; also $40 gold ore from the Pewabic mine, Jamestown. There are four blocks of gray copper ore from the Yellow Pine mine, one of the largest in Colorado, which ore runs from 400 ounces of silver per ton. The blocks weigh altogether about 2000 pounds, and are grand specimens, being literally filled with the ore. The Richmond mine, being determined to contradict the knife-blade theory applied to the Boulder County tellurides, has sent a block to show the width of the pay-streak. It is a foot or more wide and three feet long, and is full of telluride associated with mispickel. The Marshall Coal Company shows some large blocks of the lignite coal worked near the Boulder, apparently of good quality; also, some specimens of good building-stone from the same locality.

GILPIN COUNTY.

This county has a small stand exhibiting some splendid blocks of gold and silver-bearing galena and copper and iron pyrites. A large obelisk, the column colored gold and the base silver, graphically represents in mass the gold and silver mined since 1859, and given as gold, $35,500,000, and silver, $2,850,000; while last year, $2,290,000 gold and $250,000 silver were obtained.

PUEBLO COUNTY.

The exhibit of this county is chiefly of a manufacturing character. Although, as is well known, it contains considerable mineral wealth, it is much of it undeveloped, and unquestionably its chief attraction is in that wonderful, mushroom-like growth called Pueblo, which only three years ago contained but 3000 souls, while now it is claimed that there are at least 20,000 in the combined towns. Here, a vast center of manufacturing industry is rapidly forming, and already it can boast of two colossal enterprises for the treatment of the various ores containing the precious metals, and steel and iron-works which promise to reach large proportions in the future. Indeed, the facilities which Pueblo offers to manufacturers are very great. Her railroad connections are already extended directly northward, eastward, and westward, and will soon be opened to the south, and this by no mere monopoly, but by means of railroads between which there is severe competition. The only exhibits shown at present of any consequence are those of the Pueblo Smelting and Refining Company, the Colorado Coal and Iron Company, and the Colorado Machinery Company, mentioned before. Twenty-four thousand pounds of refined and manufactured lead are shown by the former, consisting of sheet, rod, and tube lead, and the exhibit has excited much favorable comment from Eastern manufacturers and merchants. The second-named company exhibits a collection of its products, namely, steel rails, blooms, and bars, with various sized nails of good quality. The raw materials used are also shown, but come chiefly from the neighboring county, Fremont. One large block of pure magnetite weighing about 1000 pounds is especially fine. The exhibit is fenced in by steel rails twisted closely when cold, and which do not show a single crack or flaw. These exhibits are highly important, as showing that, by the investment of capital, the State need not go out of its own border for many things which both had and have to be imported at great cost from the East.

OLD MEXICO.

Among the latest additions are some most magnificent and valuable specimens of ruby, brittle, and native silver. They are Batopilas ores from the Roncesvalles and San Miguel mines. Among them are specimens showing silver to the value of $25,000 per ton. One is especially worthy of notice, being a large sheet of native silver fully one quarter of an inch thick.

A small collection of carbonate ores, from Carbonate, the new camp in Garfield County, is shown, but is too small for special mention. The Union Pacific Railroad has a very fine exhibit of specimens, chiefly of a mineralogical character, and taken from the various mining districts penetrated by the railroad. There are some fine specimens of fossil palm-wood, generally incrusted on the interior with large crystals of quartz, and in some cases azotized. The specimens are seldom labeled, unless we except the cards printed with the imperious mandate, "Hands off!" so worthy of this company. The Richmond & Danville Railroad has also lately appeared with its splendid display of the riches to be found along its route; but this exhibit has already been shown twice in the East, and has doubtless been described before this by an abler pen. It is more calculated to draw capital away from us than to attract it.

MONTANA TERRITORY.

Mr. J. B. Read, the Commissioner for this exhibit, has kindly furnished me with the following particulars about the mines which are represented here, and which I may say are chiefly situated in the Butte District. The Bell mine is 400 feet down in its new shaft, where the vein measures from 8 to 24 feet thick, and is all pay ore. A splendid block was shown weighing over 200 pounds, and covered with native silver, containing about $250 worth of it, and 50 per cent of copper. The mine has a 60-ton smelter in operation, and ships 10 tons of matte per day. The Lexington is 500 feet deep, and is a silver and gold-bearing quartz-vein, a true fissure in granite. It has 60 stamps in operation. The output from January 1st for seven months has been $742,000. The ore pulps $55 per ton. The mine showed some splendid specimens, many containing visible native silver. The Moulton mine also shows specimens of silver ore from a shaft 500 feet deep, and supplies a forty-stamp mill abundantly with ore. The Alice mine is one of the biggest and best. It is 800 feet deep, and keeps an eighty-stamp mill going, giving a gross output of $90,000 per month. The Anaconda is well known, and by many is considered the second best copper mine in the world after the Calumet & Hecla. The ore is a very rich sulphide (copper glance). The company is putting in machinery costing $90,000, a 500-ton smelter being part of it. There is a 40-foot vein of solid ore carrying from 20 to 70 per cent of copper.

The following mines, also reported here, have the following developments: Colusa, 400 feet deep; ore, copper and silver; 100-ton smelter. Parrott, 300 feet deep; ore, copper; produces 75 tons per day; 75-ton smelter. The Boston & Colorado smelter is also situated there, and does a large business. This district produced $7,200,000 in silver, gold, and copper last year. The Drum Lummon mine is one of the richest mines in this territory, though not in the Butte District. It was sold for $1,500,000 this year. It is to be regretted that, through a disagreement with the authorities, the fine exhibit of this mine should be now lying packed up.

Among the machinery exhibits are several useful machines shown by Fraser & Chalmers. Especially worthy of mention is the splendid Corliss engine which supplies the motive-power for the various machines in motion. There is a Frue vanning machine, also shown in operation, and, being next to the Embrey, gives a good opportunity to study the comparative merits of the two machines. A working model of a mill is shown, which is destined—so many think—to a great run in the near future. It is called the Sturtevant mill, and crushes on a different principle from the ordinary mills for this purpose. The lumps of ore are thrown against each other by two heads revolving at an enormous speed in opposite directions, thus grinding each other. There is an arrangement by which all the ore which will not pass through a 40 mesh is returned until fine enough, and a dust-chamber is attached by which the dust, of which there is a considerable quantity, and which would otherwise be lost, is retained. The company, which has works at Boston, has only one mill in operation as yet. It claims that it pulverizes 2½ tons per hour. It is situated at the Bowker Fertilizing Company's works, Brighton, Mass. It has, however, received several orders since starting here a week ago, and many good authorities have spoken highly of the machine.

DENVER, Sept. 1. A. COPELAND.

FRENCH MINING STATISTICS.

From the Bureau of the Minister of Public Works, has been recently issued a statement of the iron and coal production of France up to the end of 1881, which shows both in that and the previous year some amount of increase. The total yield of iron ore for 1881 was 3,689,000 tons, an increase of five per cent over that of 1880, which was less by 158,000 tons. The production of Algeria was 657,000 tons for 1881, an increase of 43,000 tons. Iron ore is worked in France in thirty-three departments, half of the whole amount (1,796,000 tons) being furnished by the department of Meurthe-et-Moselle. Next comes Ardeche, with 197,000; Haute Marne, 169,000; Saone-et-Loire, 162,000; Pyrenees Orientales, 133,000. Besides the increase in production, there has been a similar increase of importation from Algeria, Spain, Germany, Italy, and Belgium, the total amount being 1,287,000 tons, 119,000 more than in the previous year. The consumption of iron ore during 1881 in the various smelting-works was 4,231,000 tons, of which 6 per cent came from Algeria, and 24 per cent from foreign sources. The production of coal, anthracite and lignite, for the year was 19,766,000 tons, an increase of 582,000 tons over that of the previous year. The departments of Nord and Pas-de-Calais figure for 8,992,000 tons, followed at a respectable distance by the Loire coal-basin, with 3,616,000 tons; Gard, with 1,933,000 tons; Burgundy and Nivernais, 1,552,000 tons; Tarn and Aveyron, 1,080,000 tons; Bourbonnais. 961,000 tons. All these minor coal-fields have fallen off in their production, and the increase of the year is solely due to Nord and Pas-de-Calais. The import of fuel into France for 1881 was 10,221,000 tons, of which 5,386,000 tons came from Belgium, 3,569,000 tons from England, and 1255 tons from Germany. Coal importation has been steadily increasing for several years in France, that of 1872 being only 7,709,000 tons. The exports of coal are very small, and are as steadily decreasing, having been 603,000 tons in 1880 and 601,000 tons in 1881. The peat fuel industry is also on the decrease; for in 1872, the working of peat bogs amounted to 325,000 tons, and in 1881 to but 233,000 tons. Peat is, however, still largely used, there being upward of 1073 recognized peat-beds in the state, on which are 8400 separate workings, employing about 26,000 hands.

THE DISCOVERY OF TIN-STONE IN THE BLACK HILLS OF DAKOTA.

Written for the Engineering and Mining Journal by William P. Blake, F.G.S.

The discovery of tin ore in the Black Hills of Dakota Territory may be said to have been complete on the seventh of June, 1883, when a sample which had been forwarded by Capt. A. J. Simmons, of Rapid City, Dakota, to General Gashwiler, of San Francisco, was submitted to me for determination. This sample was an irregular fragment, weighing about half a pound, evidently broken from a larger mass. It was dark-colored, very heavy, and had no appearance of crystallization, and did not resemble any of the ores of tin which had come under my observation. It had, however, the hardness of cassiterite, and the characteristic powder or streak. Under the blow-pipe flame, upon charcoal, an abundance of globules of white malleable tin left no reason to question that the ore was mainly the oxide of tin, the mineral species known as cassiterite, which, when pure, contains over 75 per cent of metallic tin.

The fragments were more or less mixed with a feldspathic gangue or vein-stone, and some of them were incrusted with a bright green-colored coating, which resembled the crusts of emerald nickel, but which before the blow-pipe were found to consist mainly of copper carbonate. A quantitative assay of an average sample showed the presence of 40 per cent of metallic tin.

Other samples were telegraphed for, and, on their arrival, I found, in addition to the massive cassiterite, some brown and black ores, having the appearance of columbite, of ilmenite, and of wolfram, and also, a fragmen tinvoiced as "log-spar," which I at once recognized as a fragment of spodumene.

On the 25th of July, I visited the locality and made a full examination of it, and gave a short preliminary notice of the discovery in the September number of the *American Journal of Science.*

THE LOCALITY.

The discovery is in the central portion of the Black Hills, in Pennington County, about twenty miles southwest of Rapid City, two miles from Harney City, and a few miles east of Harney Peak on the backbone or dividing range of the region. It is upon a claim known as the Etta, on a mountain which I have named Tin Mountain, and is at an elevation of about 4300 feet above the sea. Harney Peak, the highest summit of the Black Hills, has an altitude of 7403 feet, according to the survey of Messrs. Newton and Jenney.

This Tin Mountain is in the midst of a very rugged country, and is drained by the tributaries of Battle Creek, one of the largest streams of the Hills. But although the peaks and ridges are rugged, the intervening spaces are comparatively smooth and open, and permit the construction of roads at small expense. The wagon-road from Harney extends up the creek to the cabins on the claim at the foot of the peak of the mountain. There is a thick growth of pine timber over the whole region, and there is an abundance of pure water in springs and in running brooks. The rocks, the vegetation of the valleys, and the climate all remind one of the mountainous parts of Northern New England.

THE GEOLOGY.

The Black Hills, rising like an island in the broad expanse of the plains, are everywhere surrounded by the outcropping edges of the sedimentary formation from the base of the Silurian upward to the Tertiary so far as they exist at the West. These formations dip gently away on all sides from the central nucleus of more ancient rocks, which rise up in a multitude of irregular peaks and broken ridges with a general northerly and southerly trend. These rocks consist chiefly of fine-grained mica-schist and micaceous sandstones, traversed by veins of quartz, which are often auriferous, although the quartz has that peculiar glassy, barren look which is seen in the quartz veins of New England, and appears utterly unpromising for the precious metal. The slates in some portions are highly charged with small brown garnets, forming perhaps twenty per cent of the mass, so that the rocks may be said to be garnet slates rather than mica slates. There is also an abundant development of staurolites and of staurolite slate. Lithologically considered, these rocks remind the geologist of portions of the White Mountain series of formations, and are probably the equivalents of the Coos group of formations, as described by Prof. Charles H. Hitchcock, of New Hampshire. By the geologists Newton and Tenney, in their Report on the Black Hills, the mica-schists of the whole region are referred to the Huronian period; and in the preliminary notice of the discovery of tin ore in Dakota, this view was accepted. Further examination of the rocks and a consideration of the subject require a modification of this opinion, and a reference of the rocks—at least, those which abound in garnets and staurolites—to the later period. There is a sufficient breadth of formation, however, to include all the formations—the Huronian as well as the Coos and later rocks. They may also be called Montalban. No limestone beds were observed, and the magnesian rocks appear to be absent.

Toward the central portion of this area of mica-schists, granitic intrusions make their appearance, and rise in rugged peaks in the midst of the slates. These granitic masses are remarkable for the extreme coarseness of their crystallization; the constituent minerals being unusually large and separately segregated. Large masses of pure quartz are found in one place and masses of feldspar in another, and the mica is often accumulated together, instead of being regularly disseminated through the mass. It also occurs in large masses or crystals, affording sheets broad enough for cutting into commercial sizes. This occurrence of mica has led to considerable prospecting of the region for mica, and numerous claims have been located and worked. This quarrying for mica on the Etta claim brought the heavy black tin ore to notice; for Tin Mountain, where it occurs, is one of these intruded masses of coarse granite. The word intruded is here used considerately; for the phenomena fully justify this conclusion as to the origin of the granite. The surrounding schists are not greatly metamorphosed from their original condition, and the transition from schist to coarse granite is sudden. These micaceous and garnetiferous schists of the Black Hills have been subjected to an enormous amount of crushing and compression, by which they have been folded and crumpled to a remarkable degree. The longer axes of these folds and wrinkles, instead of being approximately horizontal, as is usual, are, on the contrary, nearly vertical or are highly inclined. The troughs of the strata thus stand nearly on end. It results from this folding and upheaval that the structure or grain of the rocks, so far as it is imparted by the folding, is nearly vertical and at the same time is convoluted, and in consequence the formations, in wearing away by erosion and disintegration and decay, are left with a peculiarly uneven surface, presenting a succession of pointed hills and peaks rather than a series of nearly parallel ridges. This folded structure is the basis of the peculiar topography of the country. It is the cause of it. Even the quartz veins partake of the folding, as may be seen by their serpent-like outcrops, and become columnar masses extending to great depths, while their internal extension appears to be comparatively limited. This is true also of the granitic intrusions. They appear as columnar bunches rather than sheet-like veins. The structure indicates a double folding, first horizontally then vertically. These phenomena, although apparently occult and purely scientific rather than of any "practical" significance or importance, have, nevertheless, in this case particularly a direct economical and money value. They go to show that the veins which, with their schistose walls, are so crumpled up, have a great downward extension. They probably extend much deeper than their lateral extension would indicate. In fact, this is not merely a deduction from the structural form, but it is made evident to the eye by a close inspection of any of the outcrops of the schists in which quartz veins occur. If a fragment of quartz is broken out from such outcrops, its form is found to be columnar and approximately cylindrical. So also the slates break out in columnar masses, and not in flat sheets.

The gold-bearing rocks of the Deadwood region have a similar structure, and the paying portions are controlled by or follow the pitch of the folds; which pitch or inclination is not so steep as at the tin region. The granite intrusions coming to the surface form bosses or knobs, and Tin Mountain has this form, being nearly surrounded by the schistose rocks.

MINERALOGY.

The cassiterite occurs near the top of the granite mountain, and apparently occupies a central or core-like position. The massive variety is in close association with feldspar, quartz, and spodumene, while a granular form is disseminated in a massive micaceous albitic rock or greisen, which traverses the coarse granite in the form of irregular veins or bunches.

There are thus two distinct forms of occurrence of the tin ore at Tin Mountain:

1st. Massive in bunches, with spodumene, feldspar, and quartz.

2d. Granular, disseminated in a micaceous aggregate or greisen.

In the massive form, the ore is associated chiefly with the spodumene, which here attains an unusual size. It is not only in direct contact with the spodumene, but actually penetrates it, so that it appears to partly replace portions of the crystals. One of the specimens, weighing 1¼ pounds, is two thirds tin-stone and the remainder spodumene. Another specimen exhibits the tin-stone traversing the spodumene irregularly. Besides this penetration or replacement by massive ore, it is not unusual, on cleaving a mass of spodumene, to find small, flattened grains of cassiterite in the body of the crystal, often mere stains or patches on the cleavage surfaces. In this form, it has the appearance of being a secondary deposition.

Of the massive form of the ore, about one ton of fragments has been taken out. Some of the heavier masses weighed from fifty to sixty pounds. Lumps weighing three and four pounds are common. Most of the larger masses were broken by the miners. They were in fact too heavy to handle with ease. No distinct crystalline faces on these masses have yet been observed. There are small quantities of copper oxide in crusts as already described, and some mispickel has been seen, but does not appear to be an abundant or a constant associate. It is not found in the greisen, the tin ore being apparently the only metalliferous constituent in that aggregation. The ore requires a careful qualitative and quantitative analysis, which there have not yet been time and opportunity to obtain. The specific gravity of selected fragments apparently free of gangue or associated minerals, is 6·753. The streak is brownish-gray. The massive tin ore was first encountered in sinking a pit for mica, and was followed down in irregular bunches for about 15 feet, to the bottom of what is now an open cut.

The granular or disseminated form of the tin ore appears to be the most abundant and constant. The micaceous aggregate in which it occurs consists of a mixture of small scales of mica and of albite, also in small or granular masses, or in plates radially aggregated. The dominant mineral is the mica, which is in crystalline plates seldom over half of an inch across, but is without well-defined lateral planes. Its color is light greenish-yellow. It is dense and hard, and some of the plates are sufficiently clear and transparent to permit of the measurement of the inclination of the optic axes, which was found to be, in air, from 75·30 degrees to 76 degrees. This high angle and the association of the mineral with tin ore and spodumene suggested the reference of the mica to lepidolite; but no satisfactory reactions for lithia can be obtained with the blow-pipe. The weathered surfaces resemble those of the Zinnwald lepidolite, being dark colored and showing the edges of the crystals. The mass weathers well and stands out above the other minerals. It crops out boldly at intervals over the whole top of the mountain for a breadth of 100 feet or more, and penetrates the coarsely crystalline mass formed of orthoclase feldspar, quartz, and spodumene as if it had a separate and later origin, either by intrusion or segregation. The grains often occur irregularly disseminated, sometimes at the base of an aggregation of mica crystals, at the junction with the white-spar, and again it is found more sparingly in the midst of the mica crystals in thin, flattened, transparent plates, recalling to mind the inclusion of plates of tourmaline in the sheets of muscovite mica of New Hampshire and other localities. When in such thin plates, the color by transmitted light is a light clove-brown. Such small crystals are easily detached by splitting the mica plates.

The mineralization of this albitic greisen with tin ore is general throughout the mass; at least, the tin ore can be found wherever the micaceous aggregate crops out, as is shown by breaking off masses from projecting points. But when large blocks of the rock have been blasted out, as in the open cut, and fresh surfaces are exposed, the amount of ore in different parts of the mass is seen to vary considerably, and the size of

Digitized by Google

the grains of tin-stone also varies. The size of the grains most abundant is generally under one quarter of an inch in diameter. Masses are, however, found from one half to an inch in diameter, constituting in such masses more than half the weight. The proportion of albite is also variable, and the mixture presents somewhat different aspects when broken from different places, but generally the fracture shows a very brilliant, uneven surface of alternate patches of the white-spar, mica crystals, and black grains of tin-stone. The mica has a splendid silvery luster.

This albitic greisen differs from the typical greisen of the French in having albite with the mica instead of quartz, though the general appearance and mineralization with the tin ore are the same.

The greisen of France is described by M. Manhès, and later by M. Mallard in the *Annales des Mines*, sixième série, x. 325, as formed of irregular fragments of mica and of quartz appearing in the mass like a pudding-stone. It occurs at the tin mines of Vaulry, France, and is regarded as the same in origin as the veins. The tin ore of this locality occurs both in thin veins traversing granite in a schistose region, and also disseminated in the greisen.

A specimen of greisen from France, the precise locality of which is not known, greatly resembles the Black Hills greisen, but is finer in grain, the mica crystals being smaller and more irregular, and densely packed together. There is no albite, but quartz is irregularly mixed with the mica.

It is interesting to note, also, the fact that tin ore occurs similarly in New South Wales. Some of the deposits are described as micaceous dikes, with tin ore plentifully distributed in grains from the size of a pea downward. One of the dikes forms a breccia of mica and partly crystallized tin ore cemented together by oxide of iron. (*Vide* Davies, *Metalliferous Minerals and Mining*, p. 186.)

The occurrence of spodumene with tin ore is novel, not having, so far as I am aware, been before observed. The association is not only unusual, but the magnitude of the masses of spodumene exceeds all record of this species. Crystalline masses extend across the face of the open cut from two feet to six feet in length, and from a few inches to twelve and eighteen inches in diameter. Blocks too large to lift have been freely tumbled over the dump with the waste of feldspar, quartz, and mica. No well-formed small crystals of convenient size to carry away could be found. The gigantic crystals preserve the cleavage characteristics and show the common prismatic planes. The color is lighter and is without the delicate creamy-pink hue of the specimens from Massachusetts. It is very hard, compact, and tough, and is difficult to break across the grain. Some of the fragments are translucent.

The muscovite mica, which occurs in large sheets, is entirely different from that in the greisen. It is like the ordinary commercial mica, but is rarely found in clear plates large enough to give plates over three by four inches in size. The inclination of the optic axes is from 67·30 degrees to 68 degrees.

In addition to this muscovite, there is a small amount of biotite; making three varieties of mica present in the mass. But neither the muscovite nor the biotite appears to be in direct association with the tin ore.

Other minerals, with obscure physical characters, are still under examination.

(TO BE CONTINUED.)

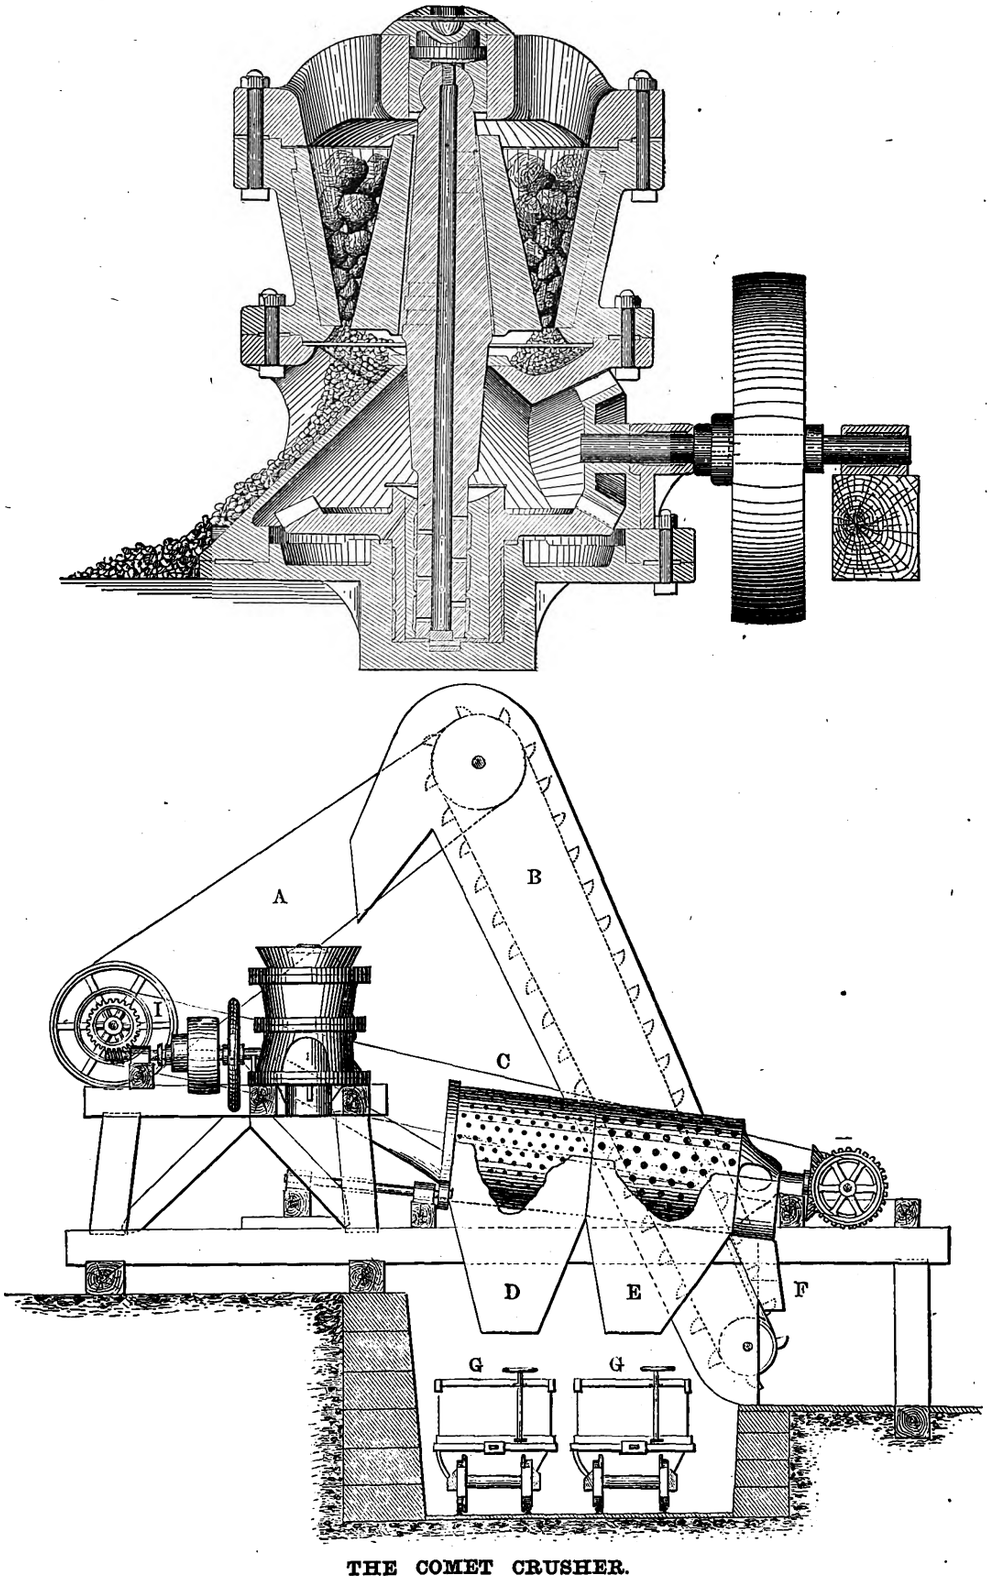
MILL FURNACE-BOTTOMS.

Experiments of interest to the iron trade have, according to English technical journals, been completed recently at the Greatbridge Iron and Steel-Works, Tipton, of the Greatbridge Iron and Steel Company, as to oxide bottoms for mill furnaces. An arrangement that has been adopted at several works in South Staffordshire, and also in Scotland, for doing away with sand bottoms and using oxides, is a hot-air chamber, patented by Mr. Job Tibbs. In constructing a furnace according to his invention, the iron plate bottom of the furnace is inclined from front to back, and also from the fire-bridge to the flue-bridge. At the back, and near the flue end of the furnace, is a hole or channel which opens out into a small supplementary chamber containing wagons, and during a heat the fused cinder formed runs off into the wagon, leaving the bed dry. An oxide bottom used under this arrangement, with a fettling of from 3½ inches to 7 inches thick, as compared with the sand bottom, will, the maker claims, produce a far superior quality of iron, and at a cost of at least 10s. per ton less, so effectual is the prevention of the accumulation of the melted cinder on the bed and its running in among the piles. The patentee claims also that whereas some cinder bottoms are used in plate and rail mills for the first heating, re-heating being accomplished on a sand bottom, by his chamber the second heating can be accomplished on the same bottom as the first. Recognizing its advantages, Mr. Scovil, of Scovil, who leases Coldbrook Rolling-Mills, St. John's County, N. B., Canada, is about to introduce this form of the oxide bottom system into the States, and for this purpose adapt the chamber to gas-furnaces in Pittsburg, where sand bottoms are now almost exclusively used. A native ore that would make as good a cinder bottom in the States as the pottery mine in Staffordshire was expected in the Port Henry ore, a high class hematite material, found in large quantities at Port Henry, on Lake Champlain, in the northeastern part of New York State. Five tons of this ore were sent over to Staffordshire, and it was to test its action that the Greatbridge experiments were conducted. There were present a number of South Staffordshire iron-masters during certain of the days during which the trial was proceeding. The five tons kept one mill furnace-bottom good, while 74¼ tons of finished iron were made from it and rolled into angles and other sections. Throughout the trial, the heat was purposely kept extreme, in view of the prospective use of the gas-furnace, and the opinion was, that the greater the heat the better. On several occasions, the bottoms, during the heats and after them, were perfectly uniform in surface and in color, and, notwithstanding the extra heat, there were no cracks or gutters; while the clearness of the piles as they were taken to the rolls showed that there had been no approach to sucking. The appearance also of the sections after passing through the rolls was all that could be desired. Altogether, the Port Henry cinder was not only as good as that o the pottery mine, but surpassed it and led makers to remark that, if the ore could be got from the States at ballast rate, it would be worth while to import it rather than continue to use the pottery mine. Touching the action of the cinder in the puddling-furnace, it may be added that the cinder from the five tons was taken to two puddling-furnaces, and lasted eleven turns. The yield in this case also surpassed that obtained where the Staffordshire materials are used, being larger by 1½ cwt. per hour for the two furnaces. The cinder from the mill furnace turned out 28 tons 3 qrs. 26 lbs. of puddled bars, and the weight of pig-iron taken to the puddling-furnace was 29 tons 9 cwt. 2 qrs. 16 lbs., or 130 heats of 4 cwt. 29 qrs. 4 lbs. each.

THE TRANSVAAL GOLD LAW.

The following is an abstract, published by *Iron*, of the law passed by the Volksraad of the Transvaal to regulate gold mining in that country. The absence of a law giving encouragement to individual enterprise has been one of the reasons for the neglect of the known rich deposits of gold in the Transvaal, and now that the state has declared that its policy will be to welcome new settlers, many experienced gold miners from Australia and elsewhere will no doubt be encouraged to take out licenses. The law begins by giving the president power to proclaim as a "gold-field" any government property on which gold may be found. If gold in payable quantities is found on a private farm, the owner has the option of taking out, within six months, a concession for the exclusive right to work it. If he does not avail himself of this privilege, the government may buy up his property at a price to be fixed by arbitration. A commissioner is to be appointed for every gold-field, over which he will have authority to keep order, and to deal with all matters arising out of the workings of the mines. He will be assisted by a diggers' committee, to be elected by the license-holders and diggers, whose interests will thereby be fully protected. Every digger and license-holder will be liable to be called on to assist in maintaining order in case of necessity, under pain of forfeiture of the license or concession. The cost of a license to dig or prospect on government ground is fixed at 10s. per month; for prospecting on private ground, with the consent of the owner, the same fee is payable, three fourths of it to go to the owner. Only one claim can be taken out by a single individual, each claim to be 150 feet square, the limits of which must be duly "beaconed." Any person, however, may buy from other claim-holders any number of claims on taking out the proper license for each. The discovery of future gold-fields is encouraged by giving any prospector who discovers gold in payable quantities five per cent of the revenue which the government may receive from such field. This revenue will be derived from the sale of licenses, from a percentage of two and one quarter per cent on all finds, and from a percentage of four per cent on the purchase money on the sale of a claim. There is a curious provision that where the sum of £300 or more has been paid for a claim, or £500 or more for improvements in the erection of machinery, and is abandoned, it shall still remain the property of the owner for a period of six months after abandonment. This provision is intended to allow the owner to reap the advantage of any discoveries which may be made within that period of reefs on adjoining claims which might possibly prove to extend into his property. The least satisfactory part of the law is that which enacts that "any colored person who sells, barters, delivers over, receives, or has in his possession rough gold shall be punished with lashes not exceeding fifty, and be imprisoned for the term of not exceeding twelve months." It is also enacted that no colored person shall have the right to hold a license or be in any way connected with the working of the gold-fields, except as laborers in service of the whites, who are prohibited, under a penalty of £500 or a year's hard labor, from paying the colored servant in rough gold, and from buying gold from any colored person under a penalty of £1000, or a year's imprisonment

THE ELECTRICAL TRANSMISSION OF POWER.—M. Marcel Deprez has recently made a most successful application of his theories on the transmission of power at Grenoble, France. This city, being in a mountainous country, is surrounded by numerous streams, developing a power which, if utilized, might be a source of great wealth. The municipality of Grenoble invited M. Marcel Deprez to repeat the experiments which he had performed with success at Munich and at the Gare du Nord at Paris. The power was supplied by the stream of the Romanche (14 kilometers from Grenoble), and thence conveyed along a copper wire of two millimeters in diameter. The mechanical effect was about 60 per cent, and the utilized power seven horse. A part of this pumped some water employed to produce an artificial cascade. The remainder M. Deprez divided between all the machines of a small work-shop, and lit besides 300 Edison lamps.



BALANCING THE WEIGHT OF THE HOISTING-ROPE IN SLOPES AND INCLINED PLANES.—Prof. J. von Hauer has called attention to a point which probably has escaped the attention of the majority of mining engineers. In a slope or inclined plane, the lower portion of which is not as steep as the upper part, the weight of the hoisting-rope is balanced. During hoisting, the relative weight of the ascending platform or car goes on increasing, while the actual weight of the rope suspended of course decreases; the reverse being the case with the descending car. By correctly choosing the curve of the incline, the weight of the rope may be balanced. Professor Hauer quotes the following example: The weight of the load was 600 kilograms, that of the empty car and platform 750 kilograms, the weight of the rope 1 kilogram per running meter, and the vertical distance between upper and lower landing 150 meters, the average dip being 32 degrees. Calculating the cycloid curve, the inclination at the upper end was found 36 degrees 17, and at the lower end 27 degrees 16 minutes, the greatest distance between the curve and the straight connecting line being 5·9 meters, and the total length of the incline 283·48 meters. The constant load thus obtained was 317·5 kilograms, against variations between the extremes of 468 and 168 kilograms with an incline of uniform pitch. In many cases, it will be cheaper to build such an incline by following the dip of a seam or the contour of the surface than to cut into the hanging-wall, or sink at a uniform incline in the case of surface planes.

THE COMET CRUSHER.

Crushers of the well-known Blake type, having a reciprocating action, do work only during a part of the time. The idea of so changing the design that work is continuous, naturally suggested itself, and it is to this class of machines that the Comet crusher belongs, the construction of which is shown in the accompanying engraving. In the jaw-crushers, the rock is broken by the approach of two plane surfaces; in the Comet crusher, the planes are converted into circular surfaces, the reciprocating being changed to the rotary motion of the inner crushing surface, which is mounted eccentrically on the shaft. The distance between a given point of the fixed outer surface and the rotating inner surface varies therefore during every revolution between the maximum and the minimum. During one revolution, therefore, the rock between the two surfaces is once subjected to crushing action, which is thus continuous.

Our section through the center of the Comet crusher clearly shows its construction. Power is applied by belt, and by gearing is transmitted to the upright shaft. The lower end of the latter enters the eccentric sleeve shown; and by changing the portable eccentric sleeve, the throw of the head may be varied to suit the exigencies of each case as to the size to which the material is to be crushed. The eccentric hub is so arranged that double wear may be got out of the gear hub. The upright shaft is made of steel, and being hollow, acts as a reservoir for the oil used for lubricating the step. Messrs. Fraser & Chalmers, of Chicago, who are the builders of the Comet crusher, attach the breaking-head to the upright shaft by means of bolts, avoiding the use of zinc. The outer circular surface is made of plates set with zinc, one of them, however, having a reverse taper, so that it can be quickly removed, and the others be got at. The ore is fed in at the top, and drops out through three discharge-openings so designed that clogging is not possible, while at the same time the gearing is protected. The frame is made in sections, so that while, strong, it can be readily transported.

THE COMET CRUSHER.

The crusher, of which five sizes are made, has an excellent record for crushing material for railroad and street ballast, for which it is principally used. It possesses one feature, which, we presume, should make it of particular value for concentration-works—that of breaking the rock into cubical form; and, as it does not grind but cracks the material, of avoiding undue breakage.

In our second drawing, we show a design for an entire plant, the points of which will be readily understood.

THE MINING AND METALLURGY OF ZINC IN THE UNITED STATES.*

By F. L. Clerc.

The Present Status of Zinc Mining and Metallurgy.—Even the most superficial inquiry into the condition of the zinc industries of the United States can not fail to expose the barrenness of the literature pertaining to the subject, and the entire absence of reliable statistics by which any comparison may be made with the state of these industries in other countries. A compilation of nominal market quotations shows little more than sudden fluctuations in the price of the various zinc products, which neither the custom-house returns nor the ruling price of foreign products will satisfactorily explain. A more careful examination into the methods of manufacture at the different works, and inquiry into the general results obtained, are apt to leave the impression that the whole subject is enveloped in mystery, belonging more properly to a secret art in the middle ages than to a growing industry of the present century. Every year or two, some European expert makes a rapid tour through the country, and announces that our ores are "equal to the best in Europe, but that our methods of mining and preparing them are extremely wasteful, and our methods of smelting are crude and extravagant, and fully a generation behind European practice in technical value and economy." It can not be denied that there is much justice in these criticisms; nor is a comparison any more favorable to this country, if we regard only the magnitude of our output or the cheapness of our products.

This inferiority can not be excused on the ground that the art of mining or that of zinc smelting is still in its infancy in this country; but it may be explained in part, first, by certain general limitations to improvement imposed by the nature of the operations necessarily involved in the smelting of zinc; and secondly, by the peculiar condition of our ore supply. In its essential features, the metallurgy of zinc is the same all over the world. The metal must be distilled in fire-clay vessels, in the presence of carbon, and condensed out of the reach of oxidizing agents. The dimensions of the distilling vessels are restricted within very narrow limits, by the nature of refractory materials and the thickness of the charge through which the necessary heat to effect reduction can be economically transmitted, and but little improvement is to be hoped for by a change in these dimensions. The operations to which the ore and products must be submitted are numerous, and the repeated handling of them can not be avoided. The recent improvements in European practice have not been the results of changes in the form of the furnaces, or in the methods of treating the ore, but have resulted from careful economies in the use of labor, fuel, and ore, and have only kept pace with the concentration of mining and smelting industries in the hands of strong companies, and are in general such as can only be introduced by companies with abundant capital, and where operations of a certain magnitude are carried on. Moreover, the policy of these companies has been, by regulating the output of the mines and the disposition of the metal, to give a steadiness to the value of both the metal and the ores, which has rendered comparatively safe such investments of capital as would otherwise have been precarious.

Such a condition of affairs can only be gradually brought about in this country, owing largely to the circumstances under which existing works were established, and to the peculiarities of the ore supply. The conditions under which smelting is carried on at the different works in this country are so various that only a general description of them is practicable; and the question of ore supply is so important that it merits more than a passing notice. The greater part of the ore used in this country is obtained as a more or less valuable by-product in the mining of lead ore; and its selling price is not controlled, either by the value of the metal it contains or by the cost of its discovery and mining. Hence its value is subject to sudden changes, and the investment of capital in zinc mining is rendered more or less unsafe. This fact has exerted a controlling influence on the methods of mining and selling the ore, on the districts most extensively worked, on the location of the principal smelting-works, and on their policy toward the ore-producers, and its effects will probably long continue to be felt on the zinc industries of the country. Its full importance may perhaps be obscured by the fact that lead and zinc ores are almost universally found associated together; but where the selling price of both ores is controlled by the value of the metal they contain, each bears its proper proportion of the cost of mining, and neither unduly depreciates the value of the other. The inland location of existing mines and works in this country, as compared with the mines and works of Europe, makes them more dependent on railroad transportation and less easily adaptable to changes in the mining and smelting centers. The metallurgy of lead is so simple that, when rich deposits of lead and zinc ore are discovered, the lead ores are quickly made available by furnaces erected to treat them, and are mined extensively; while large amounts of zinc ore are often neglected or thrown aside as worthless. The metallurgy of zinc is so complicated and expensive that it is slow to adapt itself to new localities, and the works within reach of the new ore-fields have a practical monopoly of these markets.

Sources of Supply.—The present sources of ore supply may be grouped under three divisions: the Eastern, including New Jersey, Pennsylvania, and Virginia; the Middle, including Wisconsin, Illinois, and Tennessee; and the Western, including Missouri and Kansas. These divisions correspond very nearly with distinct types of furnaces and different systems of mining, and may conveniently be treated of separately.

EASTERN DIVISION.

New Jersey.—In the Eastern division, the most notable deposit of zinc ore is in Sussex County, New Jersey, where, near the town of Franklin, there is found an absolutely unique deposit of the three rare minerals zincite (red oxide of zinc), willemite (anhydrous silicate of zinc), and franklinite, forming a rock-like mass, not unlike in appearance an eruption of granite, in which the franklinite represents the quartz, the willemite the feldspar, and the zincite the mica. This mass fills the space between limestone walls, and is crossed by numerous "trap" dikes, ranging from a fraction of an inch in thickness up to twenty feet; and is interspersed with occasional bunches of calcite, fowlerite, and other crystalline minerals. The principal mine is on Mine Hill. The ore is reached by a tunnel about 75 feet below the outcrop, and has a width of from 40 to 50 feet. It appears to be a chimney-like deposit, of the form so common in magnetite mines; no limit to it has yet been found in depth or in horizontal extension. This deposit, which has been the subject of numerous long and expensive litigations, is now controlled and worked by the New Jersey Zinc and Iron Company, with a capital of $3,000,000, which in 1880 consolidated rival claims. The ore is easily mined, and requires little selection. The cost of mining and putting it on cars should not exceed the cost of quarrying an equal amount of limestone.

An average sample would contain about 36 per cent oxide of zinc, 22 per cent metallic iron, and 11 per cent metallic manganese. Owing to its low percentage of zinc and high percentage of iron and manganese, this ore is unsuitable for the manufacture of spelter. The mechanical separation of the zinc ores has been found impracticable, on account of the intimate chemical and mechanical mixture of the different ingredients. The ore is, however, particularly adapted for the manufacture of oxide of zinc, or "zinc-white," for which purpose it is exclusively used. The works of this company are at Newark, N. J., at which point it has excellent facilities for obtaining a cheap supply of pea and slack anthracite coal, and direct communication with the mine by canal and railroad.

A smaller vein on Mine Hill, called the "front vein," has been proved for several hundred yards: it varies from 8 to 20 feet in width, and is occasionally pinched out by the wall rocks; it carries a less proportion of zincite and a greater proportion of calcite than the large vein, but its ores are of a similar character. Part of this vein is owned by the above-named company, and part is at present furnishing ore to the Lehigh Zinc-Works, at Bethlehem, Pennsylvania.

Similar veins are found at Sterling Hill, about two and a half miles distant, and have been worked to a depth of about 200 feet by the New Jersey Zinc Company, now incorporated with the New Jersey Zinc and Iron Company, and by the Passaic Zinc Company. On the property of the latter company, they are accompanied by irregular beds of beautifully crystallized calamine, from which, as it is almost entirely free from lead, a high grade of spelter is made at the works of the company at Jersey City. Mining at this point has been almost entirely suspended during the last few years, as the Passaic Company has had a contract for ore from the large vein on Mine Hill.

The shipments of zinc ore from this county for the year 1882 are reported by the State geologist to have been 40,138 tons; and the total output up to the present time may safely be stated at upward of 250,000 gross tons.

Pennsylvania.—The zinc deposits in the Saucon Valley, Lehigh County, Pennsylvania, which were once extensively worked, now produce but little ore. Their history, however, has a special interest from their connection with the introduction of spelter-making into this country, and from the fact that they belong to a class of deposits which seems to warrant a belief in their continuance to a considerable depth, and because they are a good illustration of the general effect of the characteristic feature of the ore market above referred to. Three principal deposits have been discovered, known respectively as the Ueberoth, Hartman, and Saucon mines: they occur in magnesian limestone of the Lower Silurian formation, and have many points in common, while they also present some striking differences. They were all at one time owned or controlled by the Lehigh Zinc Company, whose works were at Bethlehem, four miles distant. The Ueberoth mine, which is, so far as developments have shown, the largest, was worked continuously from 1853 up to the fall of 1876. It was for many years the main dependence of these works, and produced in the neighborhood of 300,000 tons of ore. The strata of limestone are here very much disturbed and tilted up almost to the vertical, apparently by the obtrusion of the syenite ridge of the neighboring South Mountain. The ore came close to the surface, and a very rich pocket was found in the clay above and around limestone boulders, which is estimated to have produced 100,000 tons of ore. When this body of ore was exhausted, the ore was followed down in crevices between the boulders. These crevices lie in planes parallel to the bedding of the limestone, or in planes perpendicular to it, and preserve great regularity in their position, and a parallel course for several hundred yards in a northeast and southwest direction: they are nearly vertical, and at the depth of 225 feet, to which the mine was worked, showed no signs of closing up. The ores at first were exclusively calamine and smithsonite, but at greater depth blende made its appearance, coating the walls of the crevices, and in some cases penetrating into them several feet; in other cases, segregated as rich seams, which nearly filled the cross-openings. At first, it was confined to the northeastern end of the mine, but at the lowest depth reached it could be traced almost continuously to the extreme southwestern end. The dip of the ore-body appeared to be regular, and to the southwest. Six of these parallel crevices were worked, and about as many crossings; and where they intersected, rich bunches of ore were found, some of which were as much as 60 feet across and 20 feet thick. All the indications seemed to point with increasing certainty to the existence of a backbone or underlying deposit of blende, out of the reach of the action of meteoric waters, from the continuation of which the oxidized ores have been derived. Timbering the mine was always a serious difficulty, but the greatest obstacle to be overcome was the water. Even at a depth of 40 feet, the flow was already very strong; at the depth of 150 feet, it was found necessary to put in what was then the largest pumping-engine in the world. This engine, which is a single cylinder, double-acting, condensing, walking-beam engine, with a pair of fly-wheels, has a 110-inch cylinder and a 10-foot stroke, and is calculated to work four 30-inch plunger-pumps and four 30-inch lift-pumps, with 10-foot stroke, and to take water from a depth of 30 feet. At the time it was stopped, it was running from six to seven strokes a minute, and was working three pairs of 30-inch pumps and one pair of 22-inch pumps, and was easily handling all the water that came to them. The pump-shaft and foundation for the engine were no less remarkable in their way. The latter was built up from the solid rock, 60 feet below the surface of the ground, of hewn blocks of Potsdam sandstone; the former, which measured 30 feet by 20 feet in the clear, was started on a small crevice, and timbered with 12-inch square yellow pine sticks, and divided into three compartments, and further strengthened by two open brattices of the same heavy tim-

ber. When the pitch of the vein carried it out of the shaft, the rest of the depth was sunk through solid rock.

The Hartman mine, distant about half a mile, was worked at first exclusively for calamine. Its exploitation gradually exposed a central horse of blende, which the method of mining adopted made it necessary to leave for the support of the timbers which carried the roof. The increasing importance of this blende at the lowest level worked, 150 feet, caused a change to be made in the method of mining. The mine was operated for a year after the large engine was stopped, and the last work that was done was the putting in of a slope to develop this deposit of blende. The water in the Hartman was always less strong, the pitch of the crevices less steep, and the surrounding rock less disturbed than in the Ueberoth mine; the strike of the crevices was more to the west, and the blende came nearer to the surface.

The Saucon mine, however, affords the simplest and best illustration of this form of deposit. It is distant about a quarter of a mile, and was originally leased by the Passaic Zinc Company, by whom it was sub-let to the Lehigh Zinc Company on high royalties. When the rich deposit of calamine first discovered was apparently exhausted, this sub-lease was surrendered by the latter company, and in 1875 the original lease passed to the Bergen Point Zinc Company, by whom the mine has been worked ever since. A face of blende was uncovered at the western extremity of the open pit, and the ore followed under a heavy cap of limestone for a distance of 250 feet up to the property of the Lehigh Zinc Company on the west. On this property, it was reached at a depth of 110 feet, under 100 feet of solid limestone, and was followed 150 feet farther on the course of its strike. On both properties, it was followed to a depth of nearly 200 feet. In the fall of 1879, all the property of the Lehigh Zinc Company passed into the hands of its bondholders under foreclosure of its mortgages, and in the spring of 1880 all the mining property was sold to the proprietors of the Bergen Point Zinc-Works.

The workings of these two mines, taken together, show a remarkable regularity of width, pitch, and course, and the deposit is clearly shown to be a large chimney or chute of ore of irregular cross-section, which, however, preserves a lenticular shape, the longer axis of which is about 60 feet, and pitches to the south at an angle of about 30 degrees: the transverse axis measures about 30 feet. The axis of the ore-body dips to the west-southwest with a slope of about one foot in four. The weathered outcrop has evidently given rise to the pit of oxidized ores and to certain irregular detached deposits which lie in the same course, several hundred yards beyond it.

Here, then, are three similar deposits of zinc ore, with their nearly parallel chimneys of blende and their corresponding beds of calamine, which have evidently been brought up from below, by solution in thermal springs, through crevices formed in the limestone by the gradual upheaval of the neighboring South Mountain, and have undergone subsequent alteration from the action of meteoric waters. Nearest the mountain, where the strata are most tilted and the ground most disturbed, the water is strongest and the largest deposit of calamine is found. In the Hartman mine, the strata are more nearly flat, the blende is sooner met with, and the water is much less strong; and in the Saucon mine, the blende is met with at the edge of the pit, and only moderate-sized pumps are required in working it at a depth of 200 feet. That the water in these mines comes from the same surface springs which supply the Saucon Creek, is evident from the fact that, when the big mine was abandoned, this creek shrank at once to a small fraction of its former volume, and only gradually recovered it as the mine filled up. Very careful surveys of the bed of this stream failed to discover any point at which it showed any diminution of its volume or seemed to sink into the ground. It is, therefore, very improbable that the water, having once come to the surface, found its way back into the mine. It was probably tapped in underground courses connected with the springs which give rise to the creek. This is the more probable, as the mine which has the most water is on the highest ground and is farthest from the creek, and the mine having the least water is nearest the creek. It is therefore reasonable to suppose that nearly the maximum quantity of water likely to be encountered was already handled, and that, if a solid body of underlying blende were developed, it could be profitably worked with the machinery already in place. The Saucon mine is still the main dependence of the Bergen Point Zinc-Works, but its continued working must be attended with increasing cost and uncertain risks.

The ores of this region are remarkably free from lead, arsenic, and antimony, and it is this circumstance that gives them their principal value and interest, and has been the basis of the very high reputation of the metal and oxide obtained from them. Only the richest of the ores are, in the present state of the ore market, available as spelter ores, but even the leanest of the oxidized ores produce a very fine quality of oxide. The blende is very peculiar. It is massive, and rarely shows even traces of crystallization; when pure, it has a bluish slate color, has a very characteristic conchoidal fracture, is translucent on thin edges, and gives a clear ring when struck. As generally sent to the works, it resembles broken limestone; is somewhat mixed with iron pyrites, and assays from 35 to 40 per cent of zinc. It is not easy to concentrate, both on account of its non-crystalline structure and of the pyrite it contains.

The causes which led to the extinction of the Lehigh Zinc Company and the abandonment of the two first-named mines were briefly these: the impossibility of competing successfully in the oxide market with the owners of the big mine in Sussex County, New Jersey, after the expiration of the patents covering the oxide process left them free to take the trade, or in the sheet-zinc and metal market with the Western smelters, using cheaper and richer ores, at a time when a general depression of all manufacturing enterprises made it unusually burdensome to carry the heavy bonded indebtedness incurred during a period of high prices and general inflation in acquiring mines and putting up machinery to work them. Under more favorable circumstances, it is probable that these mines could have been profitably worked for years to come; for although the pumping expenses were heavy, they were not excessive, considered as a royalty on the ore, and these charges per ton would diminish in proportion to the amount of ore mined. Now, however, it will probably be left for another generation to discover what value they still have.

Other deposits of zinc ore have been discovered in the same Silurian formation in Pennsylvania, Maryland, and Virginia, which have been worked from time to time, but have produced very inconsiderable amounts of ore. Small oxide-works were built at an early day near Birmingham, Blair County, and at Landis station, in Lancaster County, Pennsylvania, but they were soon abandoned. At the latter point, shallow beds of rich carbonate of zinc were first discovered, but were worked out. About 1876, expensive concentrating-works and two blocks of spelter-furnaces were put up, to treat the grains and kernels of crystallized blende scattered through the underlying limestone, before sufficient exploration was made to warrant such an outlay of money: they have for years been lying idle.

Virginia.—In Wythe County, along the New River Valley, zinc ore is scattered over the surface of the ground, and in connection with lead ores several thousand tons have been mined and sold to various Eastern smelters to be made into oxide. One deposit is at present worked by the Bertha Zinc Company, which has erected concentrating-works and furnaces at Martin's station, and finds a market for the limited amount of spelter which it produces, at prices above the market for Western spelter, because of its freedom from lead.

MIDDLE DISTRICT.

Illinois and Wisconsin.—With the establishment of zinc-works at La Salle, Illinois, began a revolution in the zinc trade, and Eastern smelters were soon to be restricted to the limited market for special brands of spelter. The lead regions around Galena, Dubuque, and Mineral Point had long been known and extensively worked, and large quantities of zinc ore had been discovered in prospecting; thousands of tons had been mined and stowed away in abandoned drifts, or hoisted to the surface and thrown on to the dumps, or scattered around the wash-places as worthless "jacks;" for years, ore was to be had for very little more than the cost of loading and hauling it to the smelters, and in these years were laid the foundations and established the business of those companies which dominate, if they do not control, the zinc industries of the United States. Gradually, as the ore already mined became exhausted, and other companies, attracted by the large profits there seemed to be in the business of smelting, were induced to embark in it, and as the richest deposits of lead ore were worked out and the lower price of that metal caused a falling off in lead mining, zinc ore rose in price and began to be mined for its own sake, and the condition of affairs now existing was brought about. Southern Wisconsin and the Galena District are still important zinc-producing centers, but far larger amounts of ore are now drawn from the still richer lead regions farther West. The best authorities estimate the total output of the lead region of Wisconsin prior to 1876 at 115,000 gross tons, the largest amount shipped in any one year being 19,621 tons in 1872. The output in 1880 is estimated to have been about 15,000 tons. In comparing these figures with the output of Eastern mines, it should be borne in mind that they represent a considerably larger amount of metal than their amounts would indicate, as only the richer ores are sent to the smelting-works, and the poorer are scattered about the mines. With a few exceptions (as in the case of the Illinois Zinc Company, which bought out and consolidated the different interests in an important mine in the Galena District, and by systematic working and better equipment has made it an important feeder to the works), all the mining is done by small companies, mostly unchartered associations of persons living in the immediate neighborhood. The royalties paid to the land-owners vary from one tenth to one quarter of the ore raised. Some storekeeper, farmer, or local capitalist furnishes the small amount of money needed for tools; and the men who work in the ground in winter usually engage in farm-work during the summer. The ore is generally raised to the surface by a windlass, and cleaned by hand with a "pickawee" hammer, or crushed with a "bucking-iron" on a flat stone, or by an itinerant horse power crusher, and is concentrated by sluicing and hand-jigging, and is then exposed for sale. The smelting companies which draw their ore supply from this district have their resident or traveling agents, who examine the ore as it is raised, and either contract for the output of the "diggings," or buy the ore in the ricks. Most of the miners are poor and unable to work their diggings to good advantage, or to hold their ore long after it is cleaned. The output from any given locality is small, but the aggregate is very considerable. The ore raised in this region varies greatly in quality. What has been said above refers particularly to the shallower deposits, or the old abandoned lead workings where water is not troublesome. There are shallow deposits of "dry bone" (carbonate of zinc) which are extensively worked in this way, some portions of which are very rich; but these rich layers have ordinarily a thickness of only a few inches. Above and below them, are heavier layers largely contaminated with limestone, too lean to be sold as spelter ores, which can not be concentrated. The mining for the rich ores alone is seldom very profitable, and large amounts of the lean ores are still scattered through the mines above and below ground. If a reasonable market could be found for this, many mines could be worked which are now abandoned. In 1879-80, three or four thousand tons were shipped by the Lehigh Zinc Company to Bethlehem and made into oxide. When proper care was taken to keep out any material that would discolor the oxide, a very fair quality of paint was made, and a yield of from 30 to 33 per cent was obtained. Within the year, oxide-works have been erected at Mineral Point, to run on this material.

This district, which is called the Upper Mississippi lead region, has been known to contain lead since the beginning of this century, and lead mining has been extensively carried on for upward of fifty years, and has in some cases proved very profitable. The lead occurs in the Trenton and Galena limestones of the Lower Silurian formation, which preserve their horizontal position. It is found in vertical and horizontal crevices, of which in Wisconsin alone more than 2232 have been surveyed by Mr. James Wilson, Jr.; of these, 1325 were east and west, and 482 north and south, the remainder being irregular in strike. These crevices are associated under more than forty different groups, and most of them contain some zinc ore. The east and west openings are found to be most productive, and the lowest contain the greatest proportion of blende. Where the blende is associated with galena, it is capable of being brought up to a high percentage at the mines; but where the two ores are intimately mixed and free from gangue, they are generally bought by the smelters as mined, and separated in the dressing-works at the furnace. There is also a silicate of zinc, much mixed with galena, which is treated at the mines to a rough calcination with wood in piles,

Digitized by Google

after which it is crushed and the galena is washed out. Any thing like an accurate description of this region is out of the question. Diggings are opened, change owners, are shut down, cave in, are reopened, and abandoned: little record of the yield of particular ground is kept. The skilled miners who work here are of a roving disposition; each one who wanders away carries his secrets with him; all over the country may be seen abandoned workings of which no one knows any thing beyond vague report.

Tennessee.—In Tennessee, near Knoxville and elsewhere, deposits of zinc ore have for many years been intermittently worked, and considerable amounts of ore have been calcined and shipped to Eastern smelters (and it is now proposed to build works nearer the mines); but they may be passed over, for the reason that they have had very little effect on the metal output of the country, and for the same reason the more important deposits along the line of the St. Louis & Iron Mountain Railroad, which for many years were the principal source of supply of the Carondelet smelters, will only be alluded to.

WESTERN DIVISION.

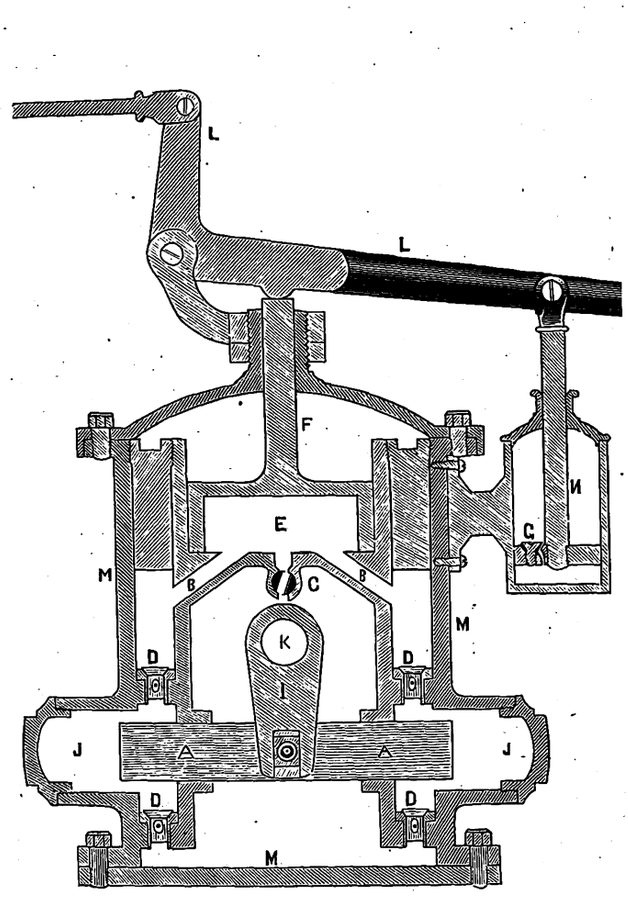
The Lead and Zinc Region of Southwest Missouri.—The lead and zinc region of Southwest Missouri is known to embrace the greater portion of Green, Dade, Lawrence, Jasper, Newton, and McDonald counties, and to it adjoins the mineral region of the eastern part of Cherokee County, Kansas. Throughout the whole of this region, both lead and zinc have been found; but the most productive district, and the only one at present worked, is confined to the northern half of Newton County, the southern half of Jasper County, and the eastern end of Cherokee County, Kansas, and to the area drained by the three streams, Center Creek, Turkey Creek, and Shoal Creek, which flow west and north and empty into Spring River within six miles of each other. In this region, the towns of Granby, on the south, and Joplin, on the north, are the centers of the principal mining activity. A very careful and intelligent account of this region, so far as it had then been developed, is to be found in the report of Dr. Adolf Schmidt and Mr. Alexander Leonhard, published in the Geological Report of the State of Missouri for the year 1873-74, to which the reader is referred. Work on the survey was interrupted in 1876, and has not since been resumed, for which reason few reliable statistics have since been published. The importance of this region as a source of zinc ore dates from the year 1871. In this year, the first regular shipments of ore were made from Granby to the zinc-furnaces at Carondelet. The discoveries of rich deposits of lead ore at Joplin in the same year, and their wonderfully rapid development, had also an immediate effect on the prosperity of this region. Here, as in Wisconsin, the discovery of zinc ore is proportional to the activity in prospecting for lead ore. The production of zinc ore for the year 1874 is given as 19,000 tons, and the present output is variously estimated at from 1000 to 1500 tons a week. There is no doubt that the latter figure is often reached, and could be maintained from present developments, except when mining is extensively interrupted either by wet weather or excessively low prices for lead or zinc ore; or that more than two thirds of the spelter made in this country comes from ore mined in this region. The ore is found in the sub-Carboniferous formation, and there is an evident connection between the known deposits of ore and the present system of surface drainage. Dr. Schmidt observed, as a remarkable fact, that the largest deposits do not lie along the principal streams, but at the heads of the smaller tributaries. The deposits of Webb City, Carterville, Empire, Galena, Sherwood, Belleville, and Blende, discovered since his examination, and now the principal sources of zinc ore, fall under the same rule. These throw new light upon the character of the mineral formations, and seem to warrant increased confidence in their extent and depth. The most important zinc mines of this region are those at Carterville and Webb City, which are really parts of the same deposit. They produce more than half of the zinc ore raised, and are worked principally for zinc ore.

As these deposits are very regular in their formation, and in a measure rule the ore market, and as the method of mining them is essentially the same as prevails throughout their entire district, a general description of them and the method of mining them will here be given. These mines lie in the open prairie, which was once cultivated in farms, about five miles northeast of Joplin, near the head of a small branch of Center Creek. They were discovered about the year 1877. Here, at a depth of from 40 to 100 feet, and often under a cap of limestone and flint 60 feet in thickness, has been found an immense deposit of zinc-blende, which has been worked continuously for over half a mile. The deposit is in the form of a bed of flint, traversed in various directions by solid bars of barren flint, but in general resembling a breccia of sharp, angular pieces of flint, closely cemented by crystallized blende, with occasional masses of bright, crystallized galena. With the exception of these bars and occasional pillars to support the roof, the whole body is blasted out. Draining is difficult, and rock drifts are sometimes necessary to unwater the ore. Dr. Schmidt considers a secondarily deposited quartzite to be the cementing material between the chert and the zinc-blende in the very similar deposits found at Oronogo; but this is certainly not the case in the best mines at Webb City nor at Sherwood, and zinc-buyers soon learn to detect the difference. Where the cementing material is pure blende, the blende breaks freely from the chert, and can be almost entirely cleaned by crushing and jigging; where the cementing material is quartzite, or black sand as the miners call it, crushing is difficult, and a satisfactory separation is impossible. The mines spread over about a section of land, 640 acres. Their weekly output is about 700 tons. The method of working them is as follows: When a good prospect is discovered in new ground, the land around it is leased from its original owners, on royalties ranging from 10 to 25 per cent, by a number of individuals, who organize various mining, or as they would more properly be called, land companies. These companies have the land divided up into lots 200 feet square, and a plat of it made; select certain lots for themselves, and throw the others open to miners. They usually start a shaft on one of their own lots, and put in a pump. If the indications continue good, many of the lots, particularly those near the pump-shaft, are quickly taken up by parties of miners, who sink shafts upon them, timber the ground, put up hoisting contrivances, furnish all supplies, and bear all expenses.

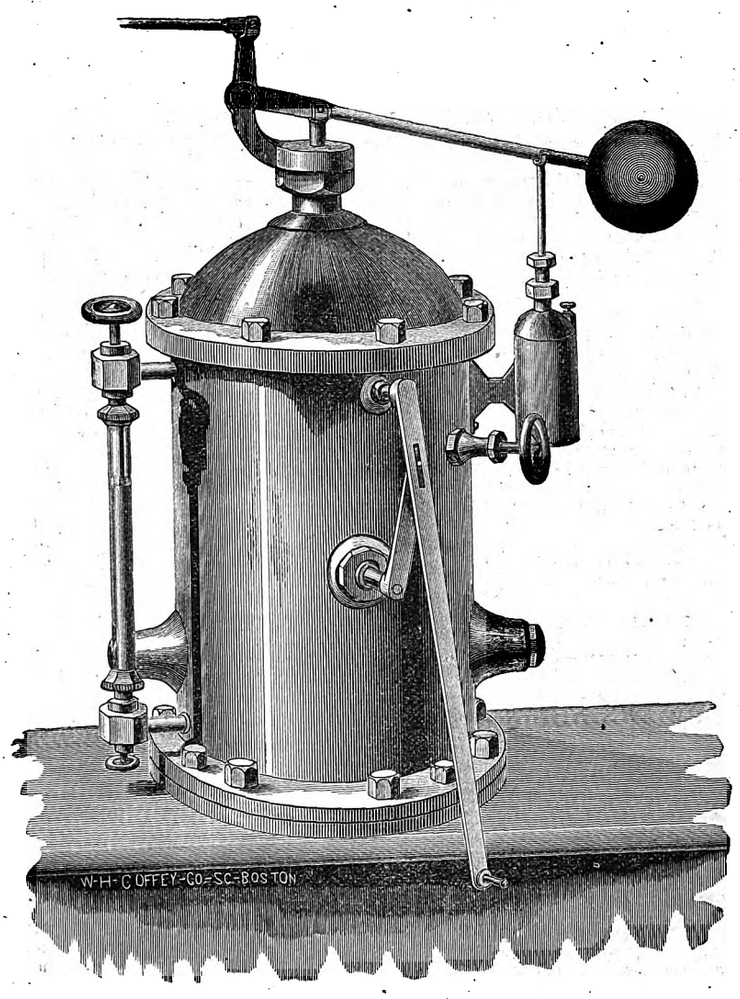
When ore is struck, it is drifted on and followed in all directions up to the boundaries of the lot in question. The ore is raised to the surface and crushed and washed by the miners, and is sold to one of the zinc or mineral buyers. It is weighed over the company's scales, and paid for to the company, which deducts a royalty of 25 per cent on zinc-blende and 50 per cent on "mineral" (galena); and if it has pumps running, a pump rent of $1 a ton on zinc ore and $2 on 1000 pounds of galena; and pays over the balance to the miners. The royalties, of course, vary with circumstances, but the above are general. The holders of lots hire other labor to do the mining, at from $1 to $1.50 a day; and usually put up crushing and washing machinery on their lots. Very often the same parties control two or three adjoining lots or fractions of lots, and sometimes neighbors go into partnership. Most companies do not allow ores to be taken from the lots on which they are mined until they have been cleaned and have paid royalty. The machinery is usually of the simplest description—a farm or small stationary engine, covered by a shed of rough boards, a small-sized Blake's breaker, set over a pair of rolls, and a horse whim or a whip. The jigs are ordinary hand-jigs, with an overheard breakstaff, working a sieve 2 by 3½ feet up and down in a box of water. The jigging is usually done by contract, and is paid for by the ton of cleaned ore. It is common to see from 10 to 20 of these jigs grouped together under a shed of poles, covered with branches of trees or rough boards. The ore as crushed yields from 10 to 50 per cent of cleaned ore, and the No. 1 grade assays about 60 to 62 per cent of metallic zinc. The tailings must in most cases be piled up on the lot from which they have come; they are drawn up into a mound with two-horse scrapers or belt elevators, and it is not an unusual sight to see jigs and crushing machinery perched on top of these mounds 15 or 20 feet above the surface level, the shafts being timbered up to a corresponding hight. Several land companies have put in fairly effective pumping machinery. Plunger-pumps working in pairs, with wooden walking-beams or bob-cranks, and driven by gearing and a crank-shaft, are the most common; but direct-acting steam-pumps, like the Worthington or Blake, have been largely introduced of late, notwithstanding the disadvantages they labor under from the gritty water of the mines. From a distance, these mines, with their swarms of busy men and heaps of tailings piled around the shafts, remind one strongly of gigantic ant-hills, and present a sight not soon to be forgotten. No one can fail to be struck with the glaring defects of such a method of mining, the absence of system, the useless duplication of machinery, the cheap yet expensive expedients, and the crowding together of conflicting operations. Below ground, the effects are, if possible, worse. Each lot is affected by the policy of its neighbors; pillars are left only when they are thought to be absolutely necessary; each miner tries to get as much as possible out of his own lot, is only interested in it as long as he expects to work it, and is not disposed to improve the value of adjoining lots by unwatering them or proving their ore. The roof and pillars are badly trimmed, and in many cases dangerous, fatal accidents being distressingly common. The officers of the land companies are generally individually interested in one or more lots, and all sorts of questions are continually arising from the conflicting interests of the company and the miners.

Looked at altogether, as the main dependence of the zinc industries of this country, such a condition of affairs is far from satisfactory, and yet it is not easy to suggest a practicable remedy. If a single company with sufficient capital could control all the lots and work them in connection with each other, the output could be largely increased, the cost of mining and dressing the ore greatly reduced, and the value of the mines kept up for a longer period, and the ore could be sold to better advantage than can be hoped for under the existing method. But this is seldom possible after the present system is once in operation; too many individuals have acquired rights in the mines, which they value at what they hope to get out of them. Nor is the present arrangement without obvious advantages in a new country, and it is seriously questioned whether any other could be as effective or as economical. When mineral is once discovered, it requires but little capital to open mines, and consequently the individual risks are small. The miners, working on their own account, with hopes of large ultimate gains, have every inducement to work hard and cheaply, and to follow every clew that may lead to the discovery of ore. There is a large body of keen, hard-working prospectors, who during the season wander from place to place, live in wagons, under tents, or in the open air, and carefully observe and follow every real or supposed indication of ore. How else, it may be asked, could prospecting be so well or so cheaply done? And there is a class of enterprising, skillful, well-to-do miners, naturally associated as partners, who have made one or more good strikes, and are always ready to take hold of any new venture that promises well, either in working a lot or in forming a land company to open new mines. Where else could be found capitalists so willing to risk their money in a speculative venture? Men of this sort are always ready and able to work themselves, or to direct the work above or below ground. How else could be obtained as willing and as watchful superintendents, foremen, and clerks? New towns are started every year, and the mining district is rapidly extending. No uniform development seems to lead to this extension; chance and the policy of the land-owners appear to be the only determining causes.

The towns of Galena and Empire, on Short Creek, in Kansas, were brought into sudden prominence in 1878, and restored the waning fortunes of the Joplin region, by the exertions of two land companies, which, on the strength of two or three rich but undeveloped prospects, laid out two rival towns, and sold town-lots without reserving mineral rights; and by extensive advertising throughout Missouri and neighboring States, created an excitement which had a purely speculative basis, but led to the collection of a large number of miners and a considerable aggregate of money. Fortunately, the results very nearly justified their most sanguine representations. The land companies then withdrew all of their remaining lots from the market, and the success of the mines was secured. They are now the principal mines for lead ore in the region, and their output of zinc is increasing.



For the discovery and working of shallow deposits, the present system seems the best that can be devised; but it is clearly not adapted to solve the problems of discovering deeper deposits or working them to advantage. No system can be defended which involves extravagant expense in mining and preparing the ore for market, forces the sale of it without



Digitized by Google

regard to its value, and renders worthless large bodies of ore that might be profitably worked by a better system; and no basis for a great industry, like the zinc industry, which makes it depend on a hundred chances independent of the price of metal, the cost of smelting, or the known deposits of ore, can be considered very safe to build upon. The caving in of a single mine, the breaking down of a pump, less activity in lead mining, or the scattering of the miners to richer camps may cause a falling off in the output of ore from which it would be very difficult to recover. That mining has on the whole been very profitable in this region, is established from the fact that the country around has steadily and rapidly increased in wealth and population. Within the last few years, three railroads, the St. Louis & San Francisco, the Missouri Pacific, and the Kansas City, Fort Scott & Gulf, have built branches through the ore-fields to each of the three towns, Joplin, Webb City, and Galena. Joplin, with its good streets, gas and water-works, machine-shops and foundries, flour and woolen mills, lead and zinc furnaces, street-cars, and extensive jobbing and retail houses, has been built almost entirely from the profits of mining.

Granby, twenty miles southeast of Joplin, presents a striking contrast. It is dependent on a single railroad, which owns much of the mining land; and the land is all leased or owned by the Granby Mining and Smelting Company. Lead ore has been extensively mined since 1856, and during the war the mines were worked for both armies. The zinc ore obtained is mainly calamine, but blende is also found. The mines are in general shallow and less troubled with water, the ores usually require less mechanical dressing than at other points in the lead region. The company receives from the men all of the lead and zinc ore, deducts the royalties paid to the railroad and its own royalties, and pays the miner on a sliding-scale, based on the price of the metallic lead and the selling price of zinc ore, for the reason that it smelts the lead ore, and at present sells the zinc ore.

This mining point is noteworthy, as it is the only one producing large amounts of calamine. The calamine is naturally rich, not much contaminated with other materials, and occurs with the lead ore in shallow horizontal openings. It was first utilized in 1871, prior to which time large amounts of it had been discovered and left in the ground or thrown aside. Since that time, it has been extensively mined, and has added greatly to the prosperity of the mines. Calamine is by nature less rich than blende in the proportion of 53 to 67 per cent; it is also much more difficult to clean when mixed with rock, on account of its lower specific gravity; but in proportion to the metal it contains, it is more valuable than blende, because it can be smelted more cheaply and the metal more perfectly extracted from it, and when mixed with blende in the furnace charge, it makes it possible to get more metal out of the blende. It is also valuable on account of the superior softness and toughness of the metal obtained from it; but it will not bear transportation to a distance as well as blende, on account of its lower percentage of metal. This ore has been at times the principal supply of the Carondelet Zinc-Works; large amounts of it have been shipped to La Salle and Peru; and in 1874, 4000 tons were shipped to Bethlehem, Pennsylvania, which yielded a little over 32 per cent of metal on the weight of the raw ore. It is less favored by the zinc-works in the neighborhood, because the freight upon it is heavier than the freight on ore from other points, and because furnaces working it can not turn out as many pounds of metal a day as when working on blende, and the output of the works is reduced. (TO BE CONTINUED.)

THE MASON REGULATOR.

THE MASON REGULATOR.

The Mason regulator, illustrated by the accompanying drawings, is designed as a governor for all kinds of direct-acting steam-pumps, engines, and water-wheels. Its principal advantage lies in the fact that it is attached directly to the piston-rod or other working part of the machine without the use of belts, pulleys, or gears. The working parts being wholly immersed in oil, and no packing being used with the exception of one bearing, the regulator will never wear out or get out of order.

The regulator, which is manufactured by the Mason Regulator Company, of Boston, consists mainly of a cylindrical shell or reservoir filled with oil or other liquid. A plunger *A A*, connected by the arm *I* to some reciprocating part of the pump or engine to be governed, works horizontally and in unison with the strokes of the main engine into the pu mp-chambers *J J*, thereby forcing the oil into the chamber *E*, whence it returns through the orifice *C*, to be re-pumped as before. In case the engine acts more rapidly than is intended, the liquid is forced into the chamber *E* faster than it can escape through the orifice *C*, thereby raising the piston *F*, which shuts the throttle through the action of the lever *L*. As the orifice at *C* can be enlarged or diminished by means of the screw-valve, it will be seen that the action of every portion of every stroke can be controlled at the will of the engineer.

The small cylinder seen at one side of the reservoir, near the top, is filled with oil or other liquid, and fitted with a piston which connects with a weighted lever. This piston is provided with a small opening which allows the oil to pass from one side to the other as it rises and falls; the duty of which is to prevent sudden or irregular movement of all the connected parts.

THE SMELTING OF ARGENTIFEROUS LEAD IN THE FAR WEST.*

By O. H. Hahn.

(*Concluded from page* 133.)

Conditions for Economical Working.—It is obvious that smelting can be conducted most cheaply at a point where ores of a different character find a joint market, and where, at the same time, railroad facilities enable the smelter to procure his fuel, flux, and other necessary materials, and ship his product at low rates of freight. Such a place is Leadville. There we have siliceous, ferruginous, and calcareous ores, which can be combined with each other in such a manner that the least possible quantity of flux is required to smelt them properly; there we have cheap fuel also. But competition has assumed such proportions at Leadville that it requires no small amount of commercial skill to purchase ores in suitable proportions to flux each other, and large smelting capacity to make the business profitable. The advent of the railroads has been of immense benefit to the camp, and the increase of capacity has reduced the cost of labor almost one half, as a comparison of the following figures will show:

The average price of fuel in 1879, when the terminus of the railroad was thirty-five miles away, was for charcoal, 14 cents per bushel of 14 pounds; coke, $36.70 per ton of 2000 pounds. In 1882, charcoal, 10½ cents per bushel; coke, $15 per ton.

The average cost of fuel per one ton of ore was: In 1879, $8.92; in 1882, $5.66.

In 1879, we had, however, much more favorable ores to smelt, which accounts for the difference not being larger in proportion. The cost of labor, when we had to worry along with two 42-inch circular furnaces in 1879 was $5.20 per ton of ore; and in 1882, when we ran five large furnaces, $2.79 per ton.

Tendency to Increase of Capacity.—This will at once show that large capacity will materially decrease the cost of labor. There is a growing tendency now to establish smelting-works in even more central points, where competing railroads intersect each other, and where the items of fuel and labor are open to still further reduction—like Denver, Pueblo, and other places. In Denver, are the extensive Grant Smelting-Works, which, for convenience of construction, effective work, cleanliness, and architectural beauty, yet seek their rival. In Pueblo, is the largest and most complete establishment in the United States, that of the Pueblo Smelting and Refining Company, with its multitude of roasting-furnaces and blast-furnaces, its sampling machinery, and its refining plant; and there is still another plant in course of construction in the same town, that of the Colorado Smelting Company. In regard to individual capacity of furnaces, the Richmond Company, of Eureka, is ahead of all others, if we may accept the statements of the Eureka *Sentinel*, which, in its issue of August 29th, 1879, gives the following items about a new furnace then building there:

	Feet.	Inches.
Length inside jackets	10	8
Width inside jackets	8	4
Hight of jackets	2	6
Hight of furnace from bottom of crucible to feed-floor	16	..
Number of tuyeres	17	..

Smelting capacity, 100 tons.

Considerable stress is laid on the number of bars which this furnace will produce per shift. I should not like to run a furnace of such dimensions; not that I care for the inside length of the jackets, but the width is monstrous, and must require a blast of five pounds to the square inch to penetrate the charge. I hope, for the intelligence of the constructor, that the *Sentinel* is in error.

Furnace Reactions.—The reactions taking place in the blast-furnace have been so often described that it is superfluous to go over the same ground again.

Operating Lead Furnaces.—In regard to furnace manipulations, only a few remarks need be made. In blowing in a furnace, it is advisable, after the hearth has been heated up sufficiently, to charge it with alternate layers of fuel and bullion, and afterward with light charges of smelting mixture and slag, to the top, before turning on a weak blast. The hearth should contain so much bullion that the latter will rise to the top of the hearth in the channel forming the automatic tap. A hearth of 3 by 6 feet 6 inches by 30 inches deep requires nearly 11 tons of bullion to fill it up. I have had occasion, however, several times to blow in furnaces in new districts where no bullion could be had to start with. In this case, the automatic tap was closed at its lowest interior opening with a clay plug, which was removed after the lead showed itself at the slag-spout. This is not a very agreeable operation, inasmuch as the formation of a bottom crust is unavoidable, and this can only be perforated, but not removed by skill or by force, while the furnace is in operation. As long as the communication between the furnace and the channel can be kept open by driving holes through the crust, smelting may proceed; but as soon as this method fails, it is best to blow out the furnace at once. If the furnace is in good working order, when it is *open*, the lead in the tap-channel or well must be of a bright red color; frequently it emits arsenical fumes, in which case it should be covered with lime or ashes, which may be removed before dipping or tapping. The well should also work with the blast; that is, the lead should go down in the channel when the blast is shut off and rise again as soon as the blast is turned on. This is well known by the furnace-men, who begin testing their well as soon as the lead begins to assume a dark color and a sow makes itself felt in the furnace. Usually, there is a tuyere above or near the lead-well. By taking off the cap of the tuyere-pipe and replacing it, the same object is reached as by taking off the whole blast and turning it on again. The presence of a sow makes itself also known at the top, as it begins to blaze up now and then, and as the charges refuse to descend. A change in the composition of the charge is needed, or a water-jacket which may be leaking into the furnace requires to be taken out. The cause is easily discovered and remedied by the metallurgist, yet it takes time to improve a furnace by changing the charge. In a charcoal furnace, a new slag will show itself after the lapse of two or three hours; while in a mixed-fuel furnace it will take six or seven hours. To enable the furnace-man to dip the lead in proportion to its percentage in the charge, he should be informed how much of a bar or how many bars are contained in a charge. He will then know whether he should keep his lead high or low in the hearth. If there is little lead in a charge, say seven or eight per cent, great care must be taken to prevent the lead in the hearth from being lowered so much that a crust would be formed by the chilling of matte or speiss when it gets too far below the tuyeres. Below the tuyeres, the separation of the molten masses according to their specific gravity takes place in the following order: lead, which is of course alloyed with the bulk of the gold and silver contained in the ore, at the bottom; speiss floating on the top of the lead; matte floating on the top of the speiss; and lastly slag. In most places, slag, matte, and speiss are run out together into a slag-pot, which is allowed to cool and is then emptied of its contents. The three products are separated in three distinct horizontal layers. The matte from zinciferous ores makes an exception; having a lighter specific gravity, approaching that of the slag, it does not separate in a horizontal layer, but is scattered through the slag as a scummy mass. An addition of copper pyrites establishes a perfect separation in such a case. If metallic zinc forms during a smelting operation, the blast will blow a portion of it out through the slag-hole, whence it appears in its oxidized state as yellow powder, which on cooling turns white. Another portion of the zinc is volatilized in the shaft of the furnace, and will appear as a white powder in the flue-dust.

Variations in Practice.—The manner in which smelting mixtures are made is not the same in all works, nor is the system of feeding or charging the furnaces the same. In some smelting-works, the weight of the fuel is stationary, that of the charge or quantity of smelting-mixture corresponding to the fuel variable; in others, the fuel is variable and the charge stationary; in still others, the weights of both are variable. The latter plan is an irrational one. I prefer the one where the charge is stationary and the fuel variable, because the furnace is less sensitive to a large quantity of fuel taken off than to changes of charge.

The weights of both fuel and ore charges should be adapted to the area of the furnace at the throat, covering it in thin layers. For a furnace which has an area of 4 feet 8 inches by 8 feet 2 inches at the throat, a good proportion is from 192 to 216 pounds of fuel (half charcoal, half coke) and from 800 to 900 pounds of charge, which is fed into the furnace in half-charges through two doors, and spread uniformly over the fuel. The furnace is kept filled up to the bottom of the charge-doors. The feeding is done by hand, by means of shovels; but it seems that experiments with automatic feeding apparatus ought to be renewed, as they have not had a fair trial.

The best plan for making a smelting-mixture or charge, as it is also called, is of course to mix a large number of tons of ore with iron ore and limestone, or whatever the flux may be, and then weigh out the charges to the feeder. But wherever there is a variety of ores of different character which may vary in moisture, size, and other conditions, an immediate mixture with the fluxes will hardly give a homogeneous material which will make itself felt in the slag. In this case, it is better to weigh each component part of a charge or a half-charge separately into a wheelbarrow or car, and dump it at or into the furnace. A furnace of the above dimensions will take seventy charges per twelve hours, and will require eight men to serve it.

Furnace Products.—The products of smelting may be—

1. Silver-lead, argentiferous lead, also and preferably called "base bullion" in this country, in distinction from gold and silver bullion. This is a remarkable product, and is sold to the highest bidder. There are a number (ten or eleven) of refineries in the country which make it their object to separate the silver, lead, and gold, and to utilize the by-products gained in the refining process.

2. *Speiss.*—This is not utilized anywhere in the United States.

3. *Matte.*—This is either roasted and smelted again or thrown over the dump.

4. *Slag.*—This is only partially re-used.

5. *Furnace Accretions.*—There are two kinds: wall-accretions and hearth-incrustations or sows. The former consists of sulphide of iron in combination with sulphide of zinc and sulphide of lead, and they contain a small amount of silver. They should be roasted before resmelting; but as most smelting-works have no facilities for doing this, they are usually thrown on a charge. The hearth-incrustations do not contain enough silver and lead to make it worth while to have them broken up and resmelted. They are thrown over the dump.

6. *Cleanings, Furnace Refuse.*—These are fragments of bricks with metallic lead adherent: they are roughly assorted and the waste thrown away.

7. *Flue-Dust.*—This is the most important product aside from the lead. As it contains the finest and, in some cases, the richest particles of the ore in admixture with the dust of coal and coke, it is, of course, worth while to save and rework it. Where much fine ore is smelted, as was the case in Eureka during several seasons, the formation of flue-dust amounts sometimes to 15 per cent of the weight of the ore. In the face of this, it is to be wondered at that so many hundred, nay even thousand, tons of flue-dust were blown to the winds before provision was made for saving it. The Richmond Company, at Eureka, was the first to go to work in earnest by building spacious flues for catching the dust escaping from the furnaces; the previous attempt at the Ruby Consolidated works having been a failure.

The great question heretofore has been to get the flue-dust in such a form that it will stay in the furnace and not be blown out again. Simply wetting it is not of much use, and is even injurious to the furnace, as it will form wall accretions which grow thicker and thicker very rapidly. Mixing it with slacked lime has also its drawbacks, as it contains coal-dust, which has a tendency to counteract the agglutinating power of the lime; therefore, from eight to ten per cent of lime is at least necessary to make a mortar which will harden. I have found that sulphate of iron, the copperas of commerce, is the best agglutinator, but it could only be used where it is cheap. Thoroughly incorporated with a solution of copperas and made into bricks, which are dried in the sun, the flue-dust becomes as hard as rock, and is in the best shape for smelting. I once suggested, in 1878, the use of a brick-machine to make the flue-dust into adobes (with lime, of course); but the season was too far advanced, the bricks froze, and on thawing burst, and the experiment was given up. At the Germania works, the flue-dust was sintered in a roasting-furnace,

* From advance-sheets of *The Mineral Resources of the United States*, published by the United States Geological Survey, Department of Industrial Statistics. Albert Williams, Jr., Chief of Department.

Digitized by Google

which is the best but not the cheapest way. The most common plan now is to work it up with lime and use it along with the ore as fast as it is made.

Losses.—In roasting, as well as smelting, there are certain losses which can not be avoided entirely, but which may be reduced to a minimum. In roasting an ore, it first experiences a loss in weight, owing to the chemical reactions taking place; it loses water and carbonic acid; sulphides of metal are converted into oxides, and thereby decrease in weight. If the roasted ore will then show more silver by assay than the crude ore, this would prove that no loss of silver had taken place. If roasting is carefully conducted, the loss of silver by volatilization should not be over three per cent; but antimony, arsenic, and zinc cause a much higher loss by carrying off silver along with them to an extent which, if the temperature has been too high, may approach 20 per cent. I am not in possession of correct data from works where roasting is carried on, as in Montana and Northern Arizona. The cost of roasting at Robinson, Colorado, was nearly $6 per ton.

The losses in smelting are caused by the formation of speiss, matte, and other by-products which are thrown away. Slag also will cause a slight loss in metals, even if of normal composition. Zinc-blende will increase the loss in the slag considerably. The loss by volatilization is very slight so far as the silver is concerned, and may be entirely avoided by having enough lead in the charge to "cover" the silver. It is, however, not known what exact minimal quantity of lead is required to cover a certain quantity of silver and prevent loss. Smelting in Leadville has proved the fallacy of Kerl's statement that 300 times the amount of lead is required to cover one unit of silver. The volatilization of lead is very large where charges low in lead are smelted; as in Leadville, where frequently charges containing only 7 per cent of lead are treated. The loss of silver at Leadville is between 3 and 4 per cent, while the loss of lead from all sources amounts to from 13 to 15 per cent. At the Horn-Silver works, the loss of lead is stated at 8·71 per cent, but there they treat charges richer in lead.

FURNACE, MILL, AND FACTORY.

The Chalmers & Spence Company, of this city, manufacturers of asbestos materials, has recently covered the pipes of the Brooklyn Bridge. The company has also taken a contract for covering all the boilers, superheaters, etc., of the Atlas line. These vessels were built on the Clyde, but all the covering put on by the builders has been removed and replaced by the Chalmers & Spence Company's well-known air-space covering.

The Harrisburg (Pa.) *Patriot* says that the new Harrisburg & Western Railroad Company (Vanderbilt's Southern Pennsylvania line) has purchased the Wister Furnace at Harrisburg for $60,000. The land gained by this purchase is twelve acres in extent. In accordance with the terms of sale, the furnace has blown out and stands idle; it will torn down. It is now definitely known that the Wister Furnace property is to form the site for the car-shops of the Vanderbilt road.

The Florence furnace, Mich., which has been idle for a few weeks, to allow of needed repairs, went into blast again this week.

McIntosh, Hemphill & Co., Pittsburg, are running to their full capacity in building nail machinery, nail-machines, and heavy castings. Owing to the fact that some of the factories are beginning the manufacture of nails from steel, a remodeling of the nail-machine is necessary, which is one cause for the increased demand.

The work of putting the Grace furnace, Mich., in shape to go into blast has been commenced by Messrs. Sturges, Kruse & Travers, under the supervision of Matthew Travers.

W. S. Bostwick & Co., of Pittsburg, manufacturers of brass castings, report business very brisk. They have booked orders in the last two weeks for over 50,000 pounds of car brasses. Last week, they shipped 15,000 pounds to the Mexican Central Railroad. Orders for rolling-mill work are also very numerous. They expect to begin the use of natural gas under their furnaces this week.

The Meyer blast-furnace at Fond du Lac, Wis., is to be started up on October 1st. This property has lain idle for a number of years.

Reeves Brothers, purchasers of the rolling-mill at Canal Dover, have definitely decided to remove it to Niles, O., and place it in operation. The process of shipping it has already begun, but the location in Niles has not yet been settled.

The Pottstown, Pa., *Ledger* of August 28d says that on Friday the Phœnix Iron Company made the first experiment in rolling steel, and it was entirely successful. An angle bar 3 by 4 was turned out. The company intends making a business of this, and will go into it for the purpose of supplying steel for shipbuilding. It is contemplated in the near future to erect immense steel-converting works. This will give work to a very large number of men. The change in the business necessitates this move, as steel is fast superseding iron in manufacturing, and it does not pay to buy steel ingots for rolling when it is possible to manufacture them.

Spaulding, Jennings & Co. have remodeled their plant in their rolling-mill at West Bergen, N. J. They have disconnected their three-high 9-inch train from the main engine, and are driving it independently by a Westinghouse engine of 150 horse-power. The engine is 14 by 14, and runs 300 revolutions. It stands between the train and the polishing-rolls, and drives each by a separate belt. The belt driving the train has a speed of over 7500 feet, or nearly a mile and a half per minute. This is possibly the highest recorded belt speed, and is entirely successful.

Sweeney & Son, of Wheeling, recently cast a lot of ore-crushed chills for the Ætna mill, and two large water-boshes for the Whittaker iron-works. Cox & Morrison are rushed with work, and will employ several additional men at their boiler-works next week. The foundry of J. M. Woodcock, at Bridgeport, started up last Monday. A new engine has been put in, the floor-room enlarged, and other improvements made the past six weeks, during which time the foundry has been closed. L. B. Purdy and William Blake have returned to Moundsville from Pittsburg, where they contracted for the engines, boilers, and hoisting apparatus for the Moundsville coal-works. The coal will be hoisted by two twin engines, 10-inch cylinders, 24-inch stroke. Steam will be supplied by a 43-inch boiler 22 feet long, with two 15-inch flues.

The Johnstown Street Steel Rail Company has begun the manufacture of the rails at the Cambria Iron-Works. The rail has the ordinary L face used on the street railroads, but the body and bottom are made like the T rail. This form obviates the use of wooden stringers, as the rails can be spiked directly to the cross-ties and connected by splice-bars, making a continuous rail. They are made of Bessemer steel.

The Sunbury, Pa., Nail, Bar, and Guide Iron Manufacturing Company has built a rolling-mill and nail factory at Sunbury, which will be put in operation in two weeks. The works consist of two double puddling-furnaces, one heating-furnace, one train of rolls, 15 nail-machines ready for work, and 10 more machines on the way. John Haas is president of the company.

The Columbia Liberty Iron Company is the name of the new corporation that has purchased the Columbia and Liberty charcoal furnaces and some valuable mineral lands in Shenandoah County, Virginia. Mr. Samuel G. Merrick, of Philadelphia, is one of the leading members of the new company. Mr. Jacob Wissler will become superintendent of the furnaces.

Park, Brother & Co.'s Black Diamond Steel-Works, with their 17-ton hammer, have just finished the largest steel shaft ever made in the United States. It weighs 28,000 pounds, and is 34 feet 6 inches in length. The dimensions are 16¼ inches hexagon, or six square, tapered down to 14½ inches hexagon at both ends. James Bridges and Mr. Bell superintended the manufacture. It was made for the St. Louis & Mississippi Transportation Company, of St. Louis, Mo.

It is proposed to convert the Columbus (Ohio) rolling-mill into a manufactory of truss, bridge, and structural iron. A year ago, the mill was equipped at great expense for the manufacture of steel rails, but the venture did not pay. The officers of the company, in a circular to the stockholders, say: "The time for making rails, either of iron or steel, has passed for the mills, as the larger companies, with their equipment of converters and expensive machinery, can always put rails on the market at a price that would be ruinous to the small producers. Other branches of the iron trade have been suggested, and it has been concluded, after thorough investigation, that the best field for our mill for the present would be in the manufacture of structural iron."

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

FIRST CHANCE.—The mill has been started up, and a full working force put on the mine. A shaft is sinking from the surface, to connect with the main winze (the mine now worked from the tunnel). When the connection is made, they will immediately erect one of Baker's California whims, and sink to the water-line; and after that is reached, will erect steam hoisting-works.

OLD JUDGE.—The shaft, now twenty-five feet deep, shows good ore, which assays from $12 to $35 per ton in gold.

GILA COUNTY.

GLOBE.—The mine is producing about 50 tons of ore a day, and running one stack, smelting the same. The slags of the former management assayed over five per cent in copper, while the new management claims to have reduced them to less than one and a half. A ten-ton silver smelter is erecting and about ready for operation, to work up the galena and carbonate ores of the camp. So states a correspondent of the Chicago *Mining Review*.

MACK MORRIS.—Operations have been suspended, and it is stated that the tools and other effects are for sale.

STONEWALL JACKSON.—The attempts to get the water out of the mine have not been successful.

GRAHAM COUNTY—GREENLEE GOLD MOUNTAIN DISTRICT.

GREAT WESTERN.—Work on the Olie mine, one of the properties of this company, is progressing favorably. A shaft 70 feet deep has been sunk, and it will be continued 30 feet farther, making the shaft 100 feet deep, when drifting on the vein will be commenced.

ORIENTAL.—At this mine, situated about seven miles from Clifton, there is an old open cut that was worked years ago by a prehistoric race, in which their stone hammers and other implements have been found; and about 100 feet north of the cut, there is an old Indian shaft, 15 feet deep, which shows a vein of very rich copper ore at the bottom.

PINAL COUNTY.

Mr. Zeckendorff is reported to have about 45 men at work on his copper properties at Riverside. The ores are a talcose slate, with native copper, being entirely free from oxides, carbonates, or sulphides. Concentrators are to be put up soon that will probably add not less than 10 tons of copper a day to the output of the territory. Several other claims in the neighborhood of the above property show ores averaging high in copper. West of Riverside some ten miles, is the copper property lately sold by Messrs. Jackson, Smith & Sharp, a horizontal deposit of high-grade carbonate copper ore. The new company proposes to erect smelting-works at once, and has sufficient ore supply to justify the undertaking.

SILVER KING.—A large amount of ore is produced. About 1000 tons are now on the dump.

YAVAPAI COUNTY—PECK DISTRICT.

BLACK WARRIOR.—This mine is steadily producing ore, and at the same time dead-work is kept ahead so as to maintain good reserves. Advices up to the 31st ult. report the mine looking most favorably for a regular output. The company's mill has been much improved since its purchase in May last, and is making an enviable record. Report for the last week of August shows an average chlorination of 93⅜ per cent, and of silver left in tailings 9⅜ per cent. The bullion is shipped to the company in New York, and is of high grade, usually ranging from 900 to 950 fine; recent bars, however, have fallen to an average of 860 fine, due to an increase of copper pyrites in the ore.

Mr. Archibald A Alexander, the general manager, gives personal supervision of the mill, while Mr. T. J. Eaman, superintendent, is in charge of the mines. It is proposed to resume work in the company's Tuscumbia mine at an early date. The water supply at the mill has been greatly improved by the sinking of an additional well to bed-rock, where a good flow of water was encountered. A new steam-pump has been added, and the reservoir tanks are now easily kept full.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—The official report for the week ended August 25th shows: Ore crushed, 155·9 tons; average assay value of pulp, $38.27 per ton; of tailings, $6.48. Bullion shipped, $7072.76. The west cross-cut, 1000 level, is 338 feet long, and the east cross-cut, same level, is 450 feet long. The west cross-cut No. 2, 1000 level, is in 63 feet. The south drift from bottom of winze No. 5 is in 71 feet.

STANDARD CONSOLIDATED.—For the week ended August 25th, the official report shows: Ore shipped to mills, 1407½ tons; bullion shipped, $13,663.46. The east cross-cut, 1200 level, is in 497 feet. The north drift No. 1, 1000 level, is in 304 feet, and shows 2 feet of vein. The south drift No. 2 is in 266 feet; the vein is 5 feet wide, and looks well. The west cross-cut from the north drift, 700 level, is 421 feet long, and is in hard ground. The south drift from the west cross-cut No. 1, 500 level, is 249 feet long, and shows the vein 3½ feet wide. The north drift is in 765 feet, where the vein is five feet wide. The uprise from the south drift is up 118 feet; the vein at this point is 5 feet wide. The uprise No. 2 from the north drift is up 55 feet, and shows 4½ feet of vein. The south drift No. 2, 385 level, is in 771 feet; vein 5 feet wide. The uprise from this drift is up 225 feet. The uprise from the north drift is up 225 feet. The stopes are yielding the usual quantity of good milling ore.

CANADA.

PROVINCE OF NOVA SCOTIA.

A brick of gold, weighing three hundred ounces, valued at $6000, was recently received at Halifax from the mines at Salmon River. It is the result of the past month's operations.

Digitized by Google

COLORADO.

CLEAR CREEK COUNTY.

The following is a statement of ore-shipments from Georgetown and vicinity during the month of August:

Shipments from	Tons.	Value in dollars.
Boston & Colorado Works	320	$32,528
Silver Plume Stamping-Works	182	24,388
Miners' Smelting Company	160	19,360
Morris & Noone	301	31,295
G. W. Hall & Co.	27	5,886
Lawson and Silver Creek	250	33,000
Total	1,240	$146,457

The above statement does not include any ore produced in the lower end of the county, which amount would probably swell the above statement to quite $200,000.

CORRY CITY.—The ninety-foot shaft has been pumped out and drifting started east and west. There is a fourteen-inch pay-streak, the iron ore of which assays from 49 to 63 ounces. On the tunnel level, a stope is raising over the shaft. A twelve-inch streak of ore was uncovered there for twenty feet, assaying 280 ounces. An average sample from the tunnel level drift ran 250 ounces. It is the intention to erect a twenty-ton concentrator at the mine, within the next six months. The Diamond Tunnel Company, owner of the Corry City, has made liberal concessions, whereby the lessees have every inducement to put through such an enterprise.

DONALDSON.—There are thirty-six men altogether employed in and about the mine, thirty-three being tributers and three engaged in working the tramway. The tributers pay a royalty of 30 per cent. The net product of the mine is between $3000 and $4000 per month, mostly free-milling quartz from near the surface, the ore being milled in the company's mill at Idaho Springs; the average net value of the ore, both mill dirt and smelting, being about $25 per ton. It is the policy of the company to take out as little of the concentrating ore as possible until such time as the mill at Fall River is completed, which will be some time before the coming winter. The mill, which will have a capacity of about 100 tons per day, is up and inclosed, and a portion of the machinery on the ground. It will have direct communication, by Halliday wire tramway 3800 feet in length, with the mine (the tramway being already built and in operation as far as the wagon-road in Trail Run, a distance of 2508 feet), so that the cost of getting the ore from the mine to the mill will be reduced, the minimum not to exceed 25 cents per ton. The deepest working on the mine is about 3000 feet, and altogether there are about 3000 feet of workings, including shafts and levels.

FREELAND.—The second level below the Freeland tunnel is in a little over 200 feet, and will have to be driven something like 150 feet farther to catch the ore-chute.

INVINCIBLE.—An undivided half-interest in this mine, situated at the head of Chicago Creek, has been sold for $25,000.

SUMMIT TUNNEL AND MINING COMPANY.—This tunnel, which is one of the greatest enterprises of this county, has now reached a depth of 560 feet. The company has fifteen patented lodes running at right angles with its tunnel, none of which has been cut as yet. At a meeting of the company held at Idaho Springs recently, it was decided to sell 20,000 shares, the proceeds to be expended in the purchase of drills, air-compressors, etc., to drive the tunnel as fast as possible.

EAGLE COUNTY.

GOLD PARK.—John W. Bailey has filed a writ of attachment in the United States Court against this company for $62,125, and given bonds to the amount of $125,000. The attachment is made by Mr. Bailey, who has been president of the company, to recover for money to this amount, alleged to have been loaned by him to the company. The marshal has levied upon about a dozen mines belonging to the company located on Holy Cross.

FREMONT COUNTY.

SOUTHWESTERN MINING AND MILLING COMPANY.—The property consists of a group of seven claims. The ore is an argentiferous galena carrying some gold, and the claims with additional development will become profitable producers. This company has an iron carbonate lode exhibiting more than twelve feet of carbonate ore of fair quality.

GILPIN COUNTY.

RARA AVIS.—The mill is to be started up shortly.

GUNNISON COUNTY.

A correspondent of the Denver *Tribune* writes from Irwin that the camp shows more activity in its mining interests than at any other period since its discovery. Machinery is placed and in working order in all of the prominent mines; leases and bonds are secured on some valuable properties, which are rapidly developed either in the interest of the lessees or to further their sale. The concentrators and sampling-works are running day and night, and the amount of ore shipped will not fall short of $35,000 a week. This is not inconsiderable, when it is considered that the amount shipped is produced only in development-work, advantage being taken of the present dry season to make preparations for the taking out of ore later on.

The McDonald-Wilder concentrator started its machinery on the 20th. The works have a capacity of 25 tons in twenty-four hours, and have been running without intermission since the date above mentioned. The character of the ore treated is ruby, native, and brittle silver and zinc-blende.

The Old Mexico & Durango has been shipping ore to the concentrator. The former is worked and yields large quantities of from 60 to 70-ounce ore. The Durango will start up soon, and the lower workings, about 200 feet deep, be stoped out. In this mine, there is a large, continuous body of ore about three feet wide which will mill-run 70 ounces.

The Rose & Reed Company is building its new concentrator in connection with its complete sampling-works. It has contracted to handle the Forest Queen ore, which is now, as always, a large producing mine.

The Bullion King has its machinery in place. The shaft, which will be sunk 100 feet farther before starting levels, is already 120 feet deep, with a south and north drift 150 and 60 feet respectively. The drifting is done on the vein with 100 feet of stoping to the surface in south level. The mine has already shipped about $60,000 worth of ore, and has on the platform at the present time 150 tons of concentrating ore, which runs 40 ounces, all ready for shipment as soon as the Rose, Reed & Co.'s concentrator starts. It is the intention to continue sinking the shaft all winter. In a few days, men will be placed at work in the south drift. Both drifts are started at the 100-foot level.

The Ruby Chief tunnel is driven 187 feet, and will be extended 300 feet farther, to tap the shaft at a depth of about 110 feet, the shaft being at present 100 feet deep. The company has shipped about $25,000 of ore, and has at least 100 tons of 45-ounce ore on the dump, which is hauling to our local mills. This company will work all winter.

The Oakes is working quite a force of men. This property is developed by a tunnel 430 feet; two shafts, one of 75 feet and another 30 feet, with two levels 14 and 60 feet, all the workings showing minerals in place, principally ruby and native silver. The first-class ore will mill-run 200 ounces, and there are 50 tons of 50-ounce ore on the dump. Both shafts are sunk on the vein. In the 30-foot shaft, the pay-streak is three feet wide, and in the 75-foot shaft 18 inches, and will run in both about 60 ounces. The character of the ore is principally ruby and native silver, but is also rich in chlorides and sulphurets.

Messrs. L. R. and H. Thompson, with F. W. Fuller, have bonded the old Shick & Howard extension for $40,000. A body of ore has been exposed unequaled in size by any heretofore discovered in the camp. There are two cross-cut tunnels, each of 300 feet, both cutting the vein at a depth of 200 feet below the surface. The vein is fully 50 feet wide, between well-defined walls, with a pay-streak five feet wide which will run 55 ounces, the selected ore running almost 400 ounces. The old Shick & Howard extension is on the same vein, a spur only of which is at present worked. The ore is similar in character to its neighboring location, the Oakes, namely, ruby, native, and brittle silver, with chlorides and sulphurets.

The Forest Queen has a fine plant of machinery. No more ore than sufficient to pay expenses will be taken out for the present, as it is the purpose of the company to do only development-work. The shaft, which is 225 feet deep, will be worked to a depth of 600 feet. The ore-body is changing in character, the arsenical iron as depth is gained being replaced by galena and copper, ruby and native silver being as large in quantity as previously.

LAKE COUNTY.

A movement is on foot, says the Leadville *Herald*, having in view the consolidation of the Nisi Prius, Leadville, and other lode claims on Rock Hill, together with a large tract of placer ground, the whole to be included under one management, and started out with a working capital of $100,000. The scheme has but recently been suggested, and is still undeveloped. From all that can be learned, it is favorably received, and will unquestionably secure a hearty support. Among the persons mentioned in connection with the enterprise are W. H. Stevens, of the Iron mine, Dennis Sullivan, W. H. James, Governor Grant, James Dexter, and other prominent citizens.

COLONEL SELLERS.—Work was begun on the Sellers shaft in March, 1882, and during the month of September following ore was struck. A great deal of water being encountered, considerable delay was experienced in putting in a large Cornish pumping plant. The first shipment of ore was made about six months ago, and since then the mine has produced regularly. The ore throughout the mine is a sulphide, the base varying greatly. Sometimes it is mostly iron, again zinc predominates, while occasionally galena is greatly in excess. The product of the mine is sold to the Arkansas Valley smelter.

ELGIN SMELTING-WORKS.—These works, operated by the Manville Smelting Company, are doing a very satisfactory business. The smelter has two furnaces, and is producing about twelve tons of bullion a day. The company has large contracts with a number of heavy producing mines, and has excellent prospects before it. Its largest contributors of ore are the Adlaide, Climax Contract, Argentine, Oro City, and Gonabrod mines.

HENRIETT.—Preparations are making for working the upper shaft on the Henriett claim. This shaft is situated near the eastern end line of the Henriett, has a depth of 400 feet, disclosing the first iron, and has not been worked for two years past. It is generally believed that a second body of iron and pay-ore will be found with greater depth.

IRON SILVER.—One of the most important mineral strikes reported this year has been made in the Moyer shaft of the Iron Silver Company. The ore-body shows a thickness of about eight feet, and consists of galena, carbonate, and sulphate of lead ores, with very little iron pyrites. The ore also carries some native silver.

LITTLE CHIEF.—The recently reported new strike continues to hold out well, and the prospects of quite a bonanza are daily improving. The drift running in on the ore has advanced thirty-five feet, and the face shows fine carbonate and galena ores, as well as iron ore carrying a large amount of silver. The sides of the drift also show fine ore. The ore-body, according to all reports, is from five to six feet in thickness, with a length and width still unknown.

MATCHLESS.—The mine has just opened another rich body of chloride and horn-silver ore.

MORNING STAR.—Developments are of a most encouraging nature. A new strike has been made near the line of the Evening Star, and about the center of the Morning Star claim. The mineral is carbonate of lead, and carries from 50 to 200 ounces in silver to the ton. The mine is producing about 50 tons of ore a day. The sinking of the McHarg shaft has been resumed. Both of the new steam-pumps are working admirably, and are keeping the shaft free of water without any difficulty.

NILES-AUGUSTA.—The lessee of this mine, on Carbonate Hill, is shipping iron ore in considerable quantity.

ST. BERNARD & BROOKLAND.—An injunction has been issued to prevent the consolidation of the St. Bernard Mining Company with the Brookland, primary arrangements for such a consolidation having been made at a recent meeting of the former company.

ST. LOUIS.—During the past few days, the workings of the mine have disclosed improved grades of copper ore. Included in the recent discoveries is copper glance, the first yet found in Lake County, from all that can be learned. The mine extends great promise of being a large producer of a great variety of minerals. It is a fissure-vein, and its products are totally different from those of the contract properties in this section.

LA PLATA COUNTY.

A number of gentlemen, representing mining interests in various parts of the San Juan, recently held a meeting in Durango, and perfected an organization known as the San Juan Miners' Association. The general aim of the association is to promote the varied mining interests of the San Juan in every possible way. This includes united effort on the part of the miners of the counties of La Plata, San Juan, Dolores, San Miguel, Ouray, Hinsdale, and Rio Grande to place the mineral resources in a positive and well-defined position before the world; to create a feeling of friendly rivalry between these counties in the way of county ore exhibits; and to stimulate the miners of the San Juan to make as large an annual output of ore as possible.

OURAY COUNTY.

The Ouray and San Juan Tramway will be open to teaming by September 1st. Its main line extends from Ouray to Mineral City, a distance of nine miles, with branches to Red Mountain and Poughkeepsie Gulch.

PARK COUNTY.

LONDON.—The stamp-mill has again commenced active operations, and the Frue concentrators are doing all that was expected as far as can be determined from an examination of the tailings and concentrates. From this time on, a continuous run will be made, handling on an average forty-five tons per day.

PITKIN COUNTY.

FARWELL CONSOLIDATED.—The entire property, situated at Independence, is offered for sale.

RIO GRANDE COUNTY.

SAN JUAN CONSOLIDATED.—Last week, we reported that the controlling interest in this mine had been sold for $900,000. The Colorado papers which made this statement have since contradicted it, and state the amount to have been but $150,000.

SUMMIT COUNTY.

WHITE QUAIL.—The mine, which is leased, is producing about fifty tons of ore a day, the bulk of which is sent to the Greer concentrator.

DAKOTA.

CALEDONIA.—The superintendent reports for the week ended August 26th: Ore produced, 300-foot level, 1050 tons. On the 20th inst., we discontinued stoping on the 400-foot level, and started a drift across the ledge from the header, which

Digitized by Google

has advanced 11 feet. We have just started a drift south on the ledge. The ore milled now shows an improvement.

FATHER DE SMET.—Superintendent Webber writes, under date of August 19th: Have just arrived at this place, and have been put in charge of property by Mr. Gregg. I find every thing going ahead well, and working smoothly. The mine shows up favorably as to quantity of ore, and I presume the quality is about as usual, though, of course, I can not judge much about it yet, not being familiar with this kind of ore. I inclose you the express company's receipt for bar No. 165, containing 723¼ ounces gold, the result of run of mill for the first half of August. On August 15th, we drew for $23,000.

GEORGIA.

A survey is making from Kingsberry's Mill, on the Tallapoosa, to the Bonner gold mine, for the purpose of constructing works to convey the water to the mines.

The scarcity of water still prevents full operations at the mines in Lumpkin County.

IDAHO.

COLUMBIA & BEAVER.—The company's mill will be started shortly, on Silver King ore. A few lots of ore from other properties will also be worked. It is proposed to charge $35 per ton for working ores, and to guarantee a yield of 95 per cent.

DEER CREEK SMELTER.—The concentrating-works will be completed by the middle of September. By that time, there will be sufficient ore extracted to keep the concentrators at work steadily. The amount of ore out gives a good start to the miners, who are getting more out each shift and opening new stopes.

IDAHOAN.—The mine is worked by an upper and lower tunnel. The upper tunnel is in 525 feet on four feet of ore; a continuous vein of ore followed in from the ledge, with a ninety-foot winze on ore running to the lower level. The lower tunnel and main cross-cut are in 600 feet, and the face is 300 feet below the surface. The first-class ore will average 120 ounces silver and seventy-five per cent lead. There are fully 1500 tons of second-class ore on the dump. Ore is shipped to the Hailey Sampling-Works, and sold in Salt Lake City and Ketchum. The building of the concentrator, ore-houses, and other buildings is pushed with energy.

JAY GOULD.—Some 3000 tons of second-class ore are on the dump ready to be worked by the new concentrator, now in course of construction. The main tunnel is in 825 feet, and cuts the vein at a depth of 700 feet perpendicularly, or 900 feet on the pitch of the vein.

MAYFLOWER.—This mine is worked by two tunnels, 1252 feet in the upper tunnel on a continuous vein of ore. Three shafts are sunk from the upper tunnel, 100 feet each. The lower tunnel is 1000 feet on the vein, 36 feet wide. They have shipped 950 tons of first-class ore to the Omaha Smelting and Refining Company, Omaha, since April 1st, 1883, averaging 180 ounces of silver and 65 per cent of lead. The steam-jig turns out six tons of first-class ore daily, taking seven tons of second-class ore and ledge-matter to make a ton of first-class ore. Forty-six men are employed. The monthly expenses are from $6000 to $7000.

MONTANA.—A vein of gray copper ore has been struck.

PHILADELPHIA MINING AND SMELTING COMPANY.—The output of the works at Ketchum ranges from 350 to 450 bars daily, with an average weight of 100 pounds. For the purpose of protecting the water-power against cold weather, arrangements have been made with the Guyer Hot Springs, by which a steady flow of hot water through the smelting company's ditch will be obtained.

SMOKY BULLION & OPHIR.—The concentrating-works will be ready for work this fall.

SNAKE RIVER PLACERS.—The lands of the Upper Snake River Valley, north of Eagle Rock, according to a correspondent of the Salt Lake *Tribune*, are rapidly locating for mining purposes, and miles upon miles of stakes are seen on both sides of the river. Several companies are now successfully at work, but scarcely a beginning has been made. So far, every experiment under the present process of working has been a complete success. The first company above Eagle Rock, Messrs. Edwards, Quayle & Quirk, lately made an experimental run of forty days, and cleaned up $1060, doing all the work themselves and employing no help. The other companies are doing the same in proportion. Messrs Edwards & Co. say it will take them, at the rate they have been running, about four years to work out one acre of ground. At present, the mining is confined to that part of the valley watered by the Snake River Water Company's canal, and for years to come this canal can furnish all the water needed. The canal takes its water from the South Fork of Snake River, thirty miles above Eagle Rock, and has cost the company over $50,000 to construct. It carries a stream about twenty feet wide, varying from six to twelve feet deep, and can be enlarged to any required extent, the supply of water being practically inexhaustible. The company is now furnishing water to all the miners on very easy terms, in order to encourage the working of the placers, and expects another season to be called upon to furnish water for fully one hundred claims. The contrivance for saving the gold is simple and cheap. Any jack carpenter can make the machine, and it is safe to say that the entire cost of the gold-saving apparatus is easily covered by an expenditure of less than $200. A stream of water carries the gravel through a common sluice-box having a common grizzly. Toward the end of the sluice-box, the black sand and gold-dust are carried through a hole in the bottom of the sluice into a system of shallow boxes carpeted with common burlap cloth; here the gold catches in the burlaps, which are periodically taken up and washed out in a tub and then replaced in the same boxes again. The number of machines which can be used is only limited by the number of hands employed and the volume of water at command.

WOOD RIVER.—The Bullion mine, the property of this company, is shipping twelve tons daily of first-class ore to the Omaha Smelting and Refining Company at Omaha, averaging 180 ounces of silver and 65 per cent lead. The mine has been developed by over 6000 feet of drifts, tunneling, and winzes. The mine has 700 tons of second-class ore on the dump, which will be concentrated about four tons into one ton of first-class ore. The company is working 100 men. The concentrator has been finished, and works well.

YELLOW JACKET.—The ten-stamp mill, which was erected only as an experiment, has given such satisfaction that next year a 100-stamp mill will be erected.

MAINE.

CUMBERLAND COUNTY.

A valuable feldspar mine is said to have been recently discovered in the town of Raymond, on land belonging to the estate of William Mayberry.

MEXICO.

From Parral, we have the following letter: There are new discoveries of rich ores of silver made within the municipal limits of this city almost every day. English, French, German, and American capital is largely investing in the mines in this vicinity, and new works are in course of erection to beneficiate the finds. Anastacio Porros, the mayor of Parral, is erecting a large concentration, lixiviation, and smelting-works. Frederick Stalforth, one of the leading citizens and bankers of this city, has in contemplation the erection of large reduction-works on the celebrated Veta Grande mines. Thomas Parker, of Texas, J. H. Johns, of Kansas City, and Capt. John McCasey, of New York City, are about to build lixiviation-works, some ten miles from this city, to beneficiate the ores of three old Spanish mines of great wealth, the ores of which average ninety-five ounces to the ton, while the average width of the veins is six feet. There is a great abundance of wood and water on the property.

The twenty-five stamp-mill of the Parral Milling and Mining Company is rapidly approaching completion. The general superintendent, Capt. John McCasey, has ten stamps of the new mill running. The mill operates splendidly. The erection of the Stetefeldt furnace is progressing rapidly; the chimney is finished. It is the highest in Mexico, being 103 feet above the grate-bars of the roaster. The old fifteen-stamp mill of this company is running steadily on ore from the Jesus Maria mine. Lixiviation is the process adopted. Superintendent McCasey maintains that lixiviation is the best and cheapest process that can be used to beneficiate the ores of this vicinity. The Sestin Land and Mining Company, of Carmen, Durango, is working ores by the patio process with good results. There is now on the ground all the necessary material for the erection of a ten-stamp mill, the machinery for the same having been furnished by Ribon & March, of Jersey City. N. A. Cowdrey is the president of this company; L. C. Palmer, general manager; and C. H. Ward, superintendent. The Philadelphia syndicate is pushing work on the Gilarania. A depth of 240 feet, and in good ore, has been attained. Parral promises to be a very lively camp this winter.

PARRAL, MEXICO, Aug. 23. M. H. LEWIS.

The Mexican *Financier* says that Major Halliday, of St. Louis, has bought a large number of gold and silver mines in the State of Guerrero, and has started for the States by the overland route through Querétaro, San Luis Potosi, and Monterey, to purchase the machinery and material for three separate plants to work the mines according to the best modern methods. The plants will comprise reduction-works, smelters, and amalgamation-pans.

With a few exceptions, says a correspondent of the Mexican *Financier*, the mines at Pachuca are looking well, and there appears to be a general expectation of a boom shortly. Holders of shares will not sell except at prices considerably above market offers, and there appears to be a general determination to hold on for the rise. Santa Gertrudis is giving good results, those from the south lode especially being eminently satisfactory. The majority of the shareholders are greatly dissatisfied with the careless superintendence and want of proper economy on the part of the direction in supplying sufficient timber to render the shaft secure, a fault which caused the recent caving in of the shaft.

The Encino mine is going on well, and rich developments are expected shortly.

The New Rosario also looks promising and is worked steadily. Several mines in this neighborhood are not now running, from want of capital, notably the California. If outcroppings are any indication of the riches concealed below, then this writer says that the legendary output of the Conde de Regla is in a fair way of being surpassed.

There are several other good undeveloped mines around the neighborhood of Pachuca and El Chico, but until within the last two or three years it was not safe for the foreigner to prospect even, much less work a mine.

Another correspondent states that the Progreso hacienda has at last started up. What the results of their very much mixed ancient and modern methods will be, remains to be seen.

The Gertrudis has recently had quite a bit of bad luck, caused by the heavy rains, about 100 varas of the San Miguel shaft having caved. It is the intention to sink a new shaft at once.

The Anglo-Mexican Copper-Works seem to have a brilliant future. They are hurrying out a No. 1 copper very fast.

The Pachuca River Company is pushing on its operations at a very rapid rate. The concentrating machinery is nearly all erected.

La Blanca mine is sinking its perpendicular shaft fast. It is now down about 100 varas.

San Cayetano el Bordo, under its new management, has taken quite a step up, though considerable work has been done building walls, sinking a new shaft, etc. At the half-yearly stockholders' meeting, a good cash balance was shown.

REAL DEL MONTE.—A dispatch from the City of Mexico states that it is reported that an American syndicate has purchased this company's mines at Pachuca for $4,000,000. The Real Del Monte Company has turned out a success.

MICHIGAN.

The Marquette *Mining Journal* gives the following table, which exhibits in gross tons the total lake shipments of iron ore from upper peninsula ports the present season, up to and including August 29th, together with the amount shipped from the same ports during the correspouding period of last year:

Name of port.	1882.	1883.
Escanaba	1,159,759	875,783
Marquette	655,410	417,985
L'Anse	39,245	42,305
St. Ignace	27,095	19,476
Total	1,881,509	1,355,549

Showing a decrease of 525,950 gross tons.

CHAMPION.—At this mine, the work is confined exclusively to sinking and opening up new ground, all the upper stopes being left intact.

HURON.—The new stamp-mill is giving most excellent satisfaction, while the mine underground never showed better for copper. The product in August will not be far from 55 tons.

IRON RIVER.—A large amount of ground is opening up. It is the intention of the management to employ a large force during the winter, principally in doing preparatory work, while in the mean time a new engine-house will be built and a plant of machinery put in. Stripping will be prosecuted all along the line, the intention being to open up the vein over its entire length—or at least so far as is found on the company's lease-hold.

NONESUCH.—Quite a number of miners are now at work, opening new ground west as rapidly as possible, while others are engaged in sending rock to the surface, which is crushed and put into the hoppers ready for the mill to start. In the mill, they are washing the sands accumulated on the floor. They are also erecting two more of Evans's slime-tables. When they are completed, the stamp-mill will be again started.

ROLLING-MILL.—Negotiations for machinery are going on. The property is to be worked to its full capacity next season.

ROPES GOLD AND SILVER MINING COMPANY.—Another shaft is sinking on this property, about 600 feet east of the Curry shaft, and which is looking well, the lode having similar proportions and characteristics as shown in its Western neighbor. Other shafts on the vein will be sunk shortly.

SPURR.—Operations have been suspended.

WEST CHAPIN.—The find of ore is just sufficient to warrant a continuance of work. An analysis of an average sample from the deposit gave: Metallic iron, 55·27; phosphorus, trace; silica, 18·51.

MONTANA.

LEWIS & CLARKE COUNTY.

A correspondent of the New York *Tribune*, speaking of Helena, says that it is not only in the center of a rich mining country, but it was itself originally a mining camp. Last Chance Gulch, in which the main street of the city is built, was formerly one of the richest placer-mining regions in the world. It is said by old-timers that $20,000,000 have been taken from the ground upon which the city stands. Two years ago, the Odd Fellows' Hall was built, and gold-dust to the amount of $1400 was washed from the dirt taken from the cellar. Every foot of ground in the city has been dug up and washed over again and again by the industrious placer-miner, and within a mile of the main street placer-mining is still going on. Evidence of mining, in the form of irregular heaps of gravel

Digitized by Google

and stones, can be seen on every hand. In the early days—a few years following 1865, when the first settlement was made—gold-dust was the only medium of exchange. Coins and greenbacks were unknown.

SILVER BOW COUNTY.

ALICE.—In the 800 foot level, at a point 105 feet west from the main shaft, the main ore-chute that has run the entire length of the Alice property, and been found in each succeeding level from the top to the bottom, has been tapped. Work in this level is pushed, and the baby-hoist on the 700-foot level materially facilitates progress, as well as cares for the water that is encountered. The winze from the 200 to the 300-foot level, at a point 185 feet east from the shaft, is expected to be finished shortly, and connection made below. The ore-body in this winze is of a uniform width of four feet, and of an average value of $100 per ton, although assays running as high as $250 and $300 have been obtained. On the 300-foot level, the same vein has been opened up both east and west; and on the completion of the winze above referred to, a body of $100 rock sufficient to run the mills two years will have been made available for easy extraction and hoisting. On the 400-foot level, prospecting is actively forwarded, to open up the same vein encountered in the levels above.

ANACONDA.—The company is pushing work on the smelter, upon which two hundred men are employed, in running the tunnel for the mill-race, building arches for the calcining-furnaces, laying the foundation-walls, grading for the concentrator, and lining the ditch with lumber.

BELL.—Some ore is hoisted from the old workings, but the greater part of the development is confined to the 400-foot cross-cut which is to connect the new workings with the old. The cross-cut is in about 105 feet, and when the length of 150 feet is attained, the connection will be finished, when active ore extraction will commence. At the smelter, the work goes steadily on, and about 40 or 45 tons of ore are treated daily.

NEVADA.

EUREKA COUNTY.

ALBION.—Some new ore has been opened out with fair indications. Prospecting is vigorously carried on by the company's men and by tributers, several of whom have good pitches.

EUREKA CONSOLIDATED.—The water in the mine is gradually lowering. The water in the old workings of the mine has gone down from above the 1200 level to about the 1300, and the shaft in the Phœnix has already been pumped dry.

LINCOLN COUNTY.

DAY.—The Pioche *Record* says: In working around the ore-chamber lately struck, three feet of copper ore were found on the east side of the ore-chamber. As soon as prospecting the ore-chamber is completed, the copper ledge will be prospected.

STOREY COUNTY—COMSTOCK LODE.

ALTA.—The work of pumping out the lower levels will occupy three or four months.

HALE & NORCROSS.—Through the stoppage of the pumps, work in the winze below the 2600 level has been a good deal retarded. It is found, however, that the donkey-pump is able to clear the winze of water very rapidly.

MEXICAN.—The rock in the uprise from the 2900 level is exceedingly hard, and rapid progress can not be made. Until this hard streak has been cut through, the water will not begin to drain out of the winze down from the 2700 level.

OPHIR.—Good headway is making in opening out on the 150 level in the old ground.

OVERMAN.—It is said that the company contemplates buying the old Petaluma mill, in order to work the ore at present extracted from the croppings by means of a tunnel near the old Overman works.

UNION CONSOLIDATED AND SIERRA NEVADA.—The joint winze is making excellent progress, and will soon reach a point where it will cut the first of the quartz streaks passed through on the 3000 level by the main west drift. These streaks presented a very promising appearance where cut on the 3000 level, and showed a considerable amount of metal, silver greatly predominating over gold.

YELLOW JACKET.—Considerable work is done in the way of exploration.

WHITE PINE COUNTY.

WHEELER TUNNEL.—The tunnel is in 647 feet, and is directed to under-cut the Original Hidden Treasure mine. The face of the tunnel has lately encountered unusually favorable material, at a vertical depth below the surface of nearly 500 feet.

OHIO.

Reports from Cleveland state that there is great excitement throughout Trumbull County over the discovery of petroleum in the village of Champion, near Warren, and people are rushing to the scene from all points of Northern Ohio.

UTAH.

EMMA.—A shipment of fifteen tons of $160 ore has just been made. The 135-foot level is opened 80 or 90 feet west from cross-cut from shaft, and 125 feet east. The ground is said to be the most promising in appearance of any that was ever found in the mine. The vein is 150 feet wide. After being driven a suitable distance, the vein will be cross-cut from this level at promising points, and at enough of them to thoroughly exploit the entire ground.

ONTARIO.—The seventh and eighth levels have both been extended westward during the last few months from 500 to 600 feet in a strong body of as fine ore as ever was found in the mine. The ninth level has not been opened at all. The pumps are taking care of the water, including the last outbreak on the eighth level, and many of them will be relieved and the expense largely reduced when the sixth level tunnel begins to be used, which will be soon.

SAMPSON.—At present, work is principally confined to the sinking of the shaft, which is nearing 180 feet in depth. There is ore on hand, and more might be taken out; but while the shaft is going down, it is not yet determined whether they will drift to the vein, which the shaft has passed through, from the 200 station, or go on to the 300 with the shaft, first.

WYOMING.

The mines at Hartville are shipping copper matte regularly, and the new Silver Crown District bids fair to prove a producing one within a very short time. The Copper King mine, in this district, is a deposit of metallic copper, which, from the indications appearing on the surface, is thought to be about forty feet wide and from 5000 to 6000 feet long. The shaft has reached a depth of 70 feet. At about 75 or 80 feet, a cross-cut will be run to ascertain the width of the body of ore in the claim. Within two miles, in a northerly direction, is a deposit of galena, silver, and gold. One mile north of this are two veins, both of which are worked. In one, are found sulphurets of copper; and in the other, copper pyrites. All these claims look well. Several placer mining districts near Laramie are producing.

PATENTS GRANTED BY THE UNITED STATES PATENT-OFFICE.

GRANTED JULY 3D, 1883.

280,349. Composition to be used in Fluxing and Protecting Molten Metals. Francis J. Clamer and Joseph G. Hendrickson, Philadelphia, Pa.
280,425. Apparatus for Concentrating Sulphuric Acid. William West, Denver, Colo., Assignor of one half to Homer Pennock, New York City.
280,541. Pick for Mining-Machines. George D. Whitcomb, Chicago, Ill.
280,544. Coal-Mining Machine. George D. Whitcomb, Chicago, Ill.
280,668. Steam Rock-Drill. Joseph W. V. Rawlins, Houghton, Mich.
280,738. Miner's Lamp. Richard W. Grimes and John Fern, Scranton, Pa.

GRANTED JULY 10TH.

280,781. Mining-Machine. Hermann Bardifzky, St. Louis, Mo., Assignor of two thirds to Andrew Brandenburger and William Tirre, same place.
280,824. Portable Forge. John P. Holt, Cleveland, O.
280,835. Compound Pump. Henry C. Langrehr, San Francisco, Cal.
280,838. Device for Burning Gaseous Fuel in Kilns. Burdett Loomis, Hartford, Conn.
280,903. Cinder-Car. Jerome L. Boyer, Columbia, Pa.
280,904. Hoisting Apparatus for Locomotive and Portable Engines. Jerome L. Boyer, Columbia, Pa.
280,909. Elevator-Bucket. Henry W. Caldwell, Chicago, Ill.
280,934. Ore-Concentrator. Artemas A. Kent, Denver, Colo.
280,954. Combined Steam-Boiler and Crucible-Furnace. Alexander Riegler, Cincinnati, O.
280,955. Combined Metallurgical Furnace and Water-Heater. Alexander Riegler, Cincinnati, O.
280,971. Steam Rock-Drill. Amos Stevens and Arthur L. Stevens, Philadelphia, Pa.
280,983. Tube-Coiling Machine. E. Walter Whitlock, New Haven, Conn.
280,994. Sampling Apparatus. George S. Andrus, Columbia, Colo.
280,997. Air-Compressor. William A. Babcock, South Coventry, Conn.
281,011. Hoisting and Conveying Machine. Alexander E. Brown, Cleveland, O.
281,022. Ingot-Buggy. Simon C. Collin, Braddock, Pa.
281,044. Process of Analyzing Pig-Iron from Blast-Furnaces. Samuel A. Ford, Pittsburg, Pa.
281,060. Amalgamator. William Hawkins and Henry R. Hawkins, Oregon, Mo.
281,063. Furnace and the Art of Working the same. James Henderson, Bellefonte, Pa.
281,074. Process of Extracting Precious Metals from Ores. A. K. Huntington, Hampstead, and Walter E. Koch, Kensington, County of Middlesex, England.
281,098. Device for Cooling Furnace-Fronts. William S. McKenna, Pittsburg, Pa.
281,159. Protecting Plumbago Crucibles. William Tatham, Philadelphia, Pa.
281,184. Roll for Slitting Iron. Howard Greer, Chicago, Ill.
281,212. Mode of Making Molds for Steel Castings. Benjamin F. Watkins, Johnstown, Pa.

GRANTED JULY 17TH.

281,242. Friction-Clutch. Hilen C. Crowell, Erie, Pa.
281,261. Steam Pumping-Engine. Harvey F. Gaskill, Lockport, N. Y.
281,272. Work-Holding Device for Metal-Slotting Machines. Charles Huke, Chicago, Ill.
281,284. Traction-Rope Railroad. Daniel J. Miller and Charles F. Findlay, Chicago, Ill.
281,366. Pile of Combined Iron and Steel. William G. Howell, Philadelphia, Pa., Assignor of one half to William Gerhard, same place.
281,385. Injector. William T. Messinger, Cambridge, Mass.
281,389. Injector. Horace B. Murdock, Detroit, Mich.
281,390. Water-Meter. Lewis H. Nash, Brooklyn, Assignor to the National Meter Company, New York City.
281,440. Traction-Rope Railroad. Adolphus Bonzano, Phœnixville, Pa.
281,446. Hoisting and Conveying Machine. Alexander E. Brown, Cleveland, O.
281,474. Rolling-Mill. Gustav Erkenzweig, Hagen, Prussia, Germany.
281,475. Rolling-Mill. Gustav Erkenzweig, Hagen, Prussia, Germany.
281,511. Machine for Grinding and Pulverizing Ores. William H. Howland, San Francisco, Cal.
281,528. Hoisting Apparatus. Henry B. Larzelere, Greencastle, Pa.
281,565. Manufacture of Explosive Compounds. Marc Eugene Sanlaville and Rodolphe Laligant, Quincié, France.
281,593. Traction-Rope Railroad. William Wharton, Jr., Philadelphia, Pa.
281,595. Rolling-Mill. Samuel R. Wilmot, Bridgeport, Conn., Assignor to himself and Willis F. Hobbs, same place.
281,596. Rolling-Mill Roll. Samuel R. Wilmot, Bridgeport, Conn., Assignor to himself and Willis F. Hobbs, same place.
281,597. Rolling-Mill Roll. Samuel R. Wilmot, Bridgeport, Conn., Assignor to himself and Willis F. Hobbs, same place.
281,625. Kiln for Firing Pottery, etc. Nancy M. Fitch, Auburn, N. Y., Assignor to Stearns Fitch, same place.
281,629. Amalgamating Apparatus. Alfred K. Huntington, Hampstead, and Walter E. Koch, Kensington, County of Middlesex, England.
281,635. Method of Treating Phosphates of Iron and Alumina. Albert H. Koefoed, New York City, and Thomas B. Stillman, Hoboken, N. J.
281,651. Combined Amalgamator and Separator. Theodore R. Timby, Nyack, N. Y.

GRANTED JULY 24TH.

281,700. Friction-Clutch. D. Randolph Kinyon, Raritan, N. J., Assignor of one half to Job C. Kinyon, same place.
281,718. Hand Rock-Drilling Machine. Henry F. Parsons, San Francisco, Cal., and Hugo Borchardt, Bridgeport, Conn., Assignors to Daniel Cook, San Francisco, Cal.
281,719. Rock-Drilling Machine. Henry F. Parsons, San Francisco, Cal., and Hugo Borchardt, Bridgeport, Conn., Assignors to Daniel Cook, San Francisco, Cal.
281,720. Mechanical Movement. Henry F. Parsons, San Francisco, Cal., and Hugo Borchardt, Bridgeport, Conn.; said Parsons Assignor to Daniel Cook, San Francisco, Cal.
281,729. Manufacture of Cast-Iron High in Carbon and Low in Silicon. Jacob Reese, Pittsburg, Pa.
281,735. Coal Cleaner. Joseph Snyder, West Pittston, and Dathan Morse, Hughestown, Pa.
281,746. Means of Attaching Elevator-Buckets to Belts. Frederick A. Wittich and Peter W. Strader, Ashtabula, O.
281,764. Furnace for Manufacturing Iron and Steel. James Henderson, New York City, Assignor of one half to Charles G. Francklyn, same place.
281,782. Ore Reducing and Separating Machine. Cortland E. Moore, Marquette, Mich., Assignor of two thirds to Henry C. Thurber, same place.
281,784. Process of Treating Iron. George Neilson, Chelsea, Mass.
281,810. Brake for Winding or Hoisting-Engines. William C. Waters, San Francisco, Cal.
281,815. Grip for Endless-Cable Ways. Levi J. Wing, Brooklyn, N. Y.
281,828. Movable Jaw for Stone and Ore-Crushers. Daniel Brennan, Jr., Orange, N. J.
281,843. Steam-Engine. Franklin D. Cummer, Detroit, Mich., Assignor to the Cummer Engine Company, Cleveland, O.
281,846. Lid for Miners' Lamps. John B. Deeds and William Mack, Terre Haute, Ind.
281,922. Rock-Drill. William H. Randall, San Francisco, Cal.
281,945. Ore-Roasting Furnace. James M. Thompson, San Francisco, Cal.
281,978. Rolling-Mill. Alfred Crandell, Pine Plains, N. Y.
281,982. Amalgamator. John T. Davis, Rahway, N. J., and Isaac Stead, Philadelphia, Pa.; said Davis Assignor to said Stead.

GRANTED JULY 31ST.

282,035. Device for Promoting Combustion in Furnaces. James E. Baker, Chicago, Ill.
282,041. Apparatus for Compressing Liquid Steel. John F. Bennett, Pittsburg, Pa.
282,042. Pump-Regulator. James H. Blessing, Albany, N. Y.
282,055. Wire-Coating for Drawing. Addison B. Clemence, Worcester, Mass.
282,064. Coke-Oven and Kiln. Friderich C. Eberley and Rudolph Richter, Denver, Colo.
282,071. Steam Motor-Engine. Harvey F. Gaskill, Lockport, N. Y.
282,073. Electric Ore-Separator. Herman Greve, St. Paul, Minn.
282,118. Production of Ferro-Phosphorus. Jacob Reese, Pittsburg, Pa.
282,131. Amalgamator. Hugh M. Thompson, St. Louis, Mo.
282,163. Mechanism for Moving Earth and Excavated Material. Howard A. Carson, Boston, Mass.
282,200. Elevated Wire Railroad. Smith H. Knapp and Alpheus E. Adams, Danbury, Conn.
282,218. Ore-Pulverizing Machine. Henry E. Parson, New York City.
282,265. Metal-Melting Furnace. George M. Bryant, Minneapolis, Minn.
282,266. Apparatus for Manufacturing Iron and Steel directly from the Ore. Henry Clay Bull, Liverpool, County of Lancaster, England, Assignor to Bull's Iron and Steel Company (Limited), same place.
282,274. Mining-Machine. Charles W. Colvin, Wilkes-Barre, Pa.
282,279. Metal Crucible. Mattison Darragh and Scudder H. Darragh, Bridgewater, Pa.
282,315. Furnace for the Manufacture of Iron and Steel and for other Purposes. James Henderson, Bellefonte, Pa.
282,342. Furnace for Distilling and Carbonizing Wood, etc. Jean A. Mathieu, Philadelphia, Pa.
282,349. External Friction Brake-Band for Hoisting Machinery, etc. Daniel H. Merritt, Marquette, Mich.
282,352. Amalgamator. Henry Moon, Thomasville, N. C.
282,382. Rock-Drilling Machine. Alfred Shedlock, Brooklyn, N. Y., Assignor to John D. Shedlock, same place.
282,387. Gas-Producer. Charles W. Siemens, Westminster, County of Middlesex, England.
282,440. Process of Distillation of Coal. William J. Cooper, Westminster, County of Middlesex, England.
282,464. Flux for Welding Metals. Wilhelm Mutter, Syracuse, N. Y.

Digitized by Google

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Sept. 7.

This week has been one of the dullest that the mining market has yet experienced. With the exception of two or three fancy stocks, the transactions have been very small. Elko Consolidated has been the most active stock dealt in, and Robinson and Sonora Consolidated record large dealings. Prices have not materially changed either way. Below will be found a full summary of the market. The total number of sales aggregates 133,810 shares, as against 155,652 last week.

The Comstock shares were very quiet, and were steady. California sold from 26@24c. Consolidated Virginia was moderately dealt in, and was a little weak; it sold from 60@56c. Sierra Nevada was quiet and strong, selling from $4.25@$4 45. Union Consolidated sold from $4.90@$5.13@$5, with transactions of 235 shares. Sutro Tunnel was fairly dealt in at steady prices; it sold from 19@20c.

The Leadville stocks were also quiet and steady. Amie was irregular, under a small business, selling from 15@12@14c. Chrysolite was moderately dealt in at steady prices, selling from $1.10@$1.15. Breece sold at 20c. Iron Silver was quiet and strong, selling from $3@$3.10. Leadville sold at 80c. and Little Chief at 55@50c. The transactions in both were very small.

The Bodie stocks were almost neglected. Bodie sold at 70c. assessment paid, and from 16@12@15c. assessment unpaid. Standard was quiet and irregular, selling from $5.75@$5.25@$5.38.

The Tuscarora stocks were very quiet, with the exception of Elko. Grand Prize sold at 15c. Navajo was dealt in to the extent of 300 shares at $2.90. North Belle Isle was moderately dealt in at strong prices, selling from 40@50c. Elko Consolidated was very active, and at one time quite strong; it sold from 10@16@13c.

In the miscellaneous list, Alice was quiet and steady at $2. Bassick sold at $9, with one small transaction. Eureka Consolidated was quiet and strong, selling at $7.50. Gold Stripe was quiet and steady at 7@8c. Hall-Anderson was moderately dealt in at steady prices; it sold from $1@$1.10. Horn-Silver was quiet and strong, selling from $7@$7.25. Northern Belle sold from $6@$6.13, with a small business. Robinson Consolidated was active and irregular, selling from 46@40@48@47c. Sierra Grande was also irregular, under a small business, selling from $1.05@95@97c. Silver King sold from $7@$6.75.

Alta-Montana was quiet and steady at 5@6c. Barcelona was very quiet at steady prices, selling from 34@33c. Central Arizona sold from 24@25c., with a small business. Decatur sold at 2c. Eastern Oregon was very quiet and was quoted at weaker prices than of late; it sold from 76@75c. Sonora Consolidated was actively dealt in at steady prices; it sold from 27@25c.

A sale of 250,000 shares (a controlling interest) of the United Mining Company was announced to take place at the Real Estate Exchange Sales-Room on Wednesday last. We understand that 30,000 shares were sold, but that no actual transfer of property took place. The company owns four gold and silver mines in Grand County, Colorado, near the town of Teller.

A meeting of those stockholders of the Eureka Consolidated Mining Company who are in favor of a change in the management and of having a transfer-office in this city was held at the office of R. H. Rickard, No. 32 Pine street, on Wednesday last. The meeting was well attended, some 28,000 shares being represented, and Dr. Mackenzie was appointed to attend the annual meeting of the company in San Francisco on the 15th day of October next.

We have received some favorable news in regard to the Stormont Company. The secretary reports that the company is out of debt and has a surplus of about $14,000; and that it is netting from $1000 to $3000 per month at the present time.

MEETINGS.

Rappahannock Gold Mining Company, No. 60 Broadway, Room 15, New York City. Adjourned meeting of stockholders September 14th, at a quarter past four o'clock P.M.

DIVIDENDS.

The Castle Creek Mining Company, of Idaho, has declared its sixteenth regular monthly dividend of three per cent, payable September 17th.

The Dunkin Mining Company, of Colorado, has declared a dividend (No. 16) of five cents per share, or ten thousand dollars, payable October 1st.

The Plymouth Consolidated Gold Mining Company, of California, has declared a dividend (No. 4) of fifty cents per share, or fifty thousand dollars, payable immediately at the offices in New York and San Francisco.

The Standard Consolidated Mining Company, of California, has declared its monthly dividend of twenty-five cents per share, payable on September 12th, at the Farmers' Loan and Trust Company.

PIPE LINE CERTIFICATES.

Watson & Gibson, of No. 49 Broadway, report as follows on the petroleum market:

There has been but little activity during the past week except for a very brief time on Wednesday. The fluctuations were within so narrow a range that the public were not attracted to the market.

Under the report that Grandin No. 14, which is on the extreme southwestern limit of Balltown development, was showing for a large well, the market broke to $1.06⅛. This proving to be untrue, the market reacted to $1.08⅛ under free buying of shorts. The well is now yielding only about seven barrels per hour; and as the sand is said to be of poor quality, the bulls contend that it cuts off the extension of the Balltown pool in that direction. Some important wells are drilling on the northeastern end of Balltown, near Porcupine No. 9, which will test the territory. Until these wells are in, about a week hence, no bull movement in oil is likely. If they prove small, we may look for a spirited advance. Refined oil is 8⅛, a shade higher than a week ago.

Steps have been taken by the leading oil exchanges of the country to form a central organization for the purpose of insuring a uniformity of business methods and the protection of members. The plan is, to have a central organization, to be known as the Conference of Oil Exchanges. The exchanges which have approved the preliminary work are the Oil City, the Titusville, the Bradford, and the Pittsburg exchanges, and the New York Petroleum Exchange. Each of these institutions is to be entitled to three delegates to the conference, which is to meet on the third Thursday of June in every year. Future admissions of exchanges are to be classified as follows: First class, entitled to three delegates, exchanges whose clearances average 100,000,000 barrels per month for the three months preceding the date of application for admission; second class, two delegates, clearances 50,000,000 barrels per month; third class, all other exchanges, which shall be entitled to only one delegate. One of the most important features of the new plan is the provision that "any member of the several exchanges who may be suspended or expelled from either of the exchanges to which he belongs shall likewise stand expelled or suspended from all the exchanges to which he belongs." A suspended or expelled member of any one exchange will be ineligible to membership in any other exchange in the conference. At a meeting of the members of the New York Petroleum Exchange yesterday, the proposed plan was adopted, and S. F. String, D. R. Offley, and P. B. Crosby were selected as a committee to complete the details.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Sept. 1.....	$1.08¾	$1.09⅜	$1.08¼	$1.08⅝	1,742,000
3.....	1.08½	1.08⅝	1.07½	1.08⅛	1,672,000
4.....	1.08⅛	1.08⅛	1.06¾	1.07⅜	1,641,000
5.....	1.06⅞	1.08¾	1.06⅞	1.08¼	2,027,000
6.	1.08⅞	1.08⅞	1.08¼	1.08⅜	1,953,000
7.....	1.08⅛	1.08½	1.07¾	1.08	1,311,000
Total sales.					10,346,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, September 6.

The market for copper stocks the past week shows a little firmer tendency as to prices, but continues to rule dull and inactive. There is but little stock offering for sale at present prices, and it would be difficult to fill an order for any considerable amount of the dividend-paying mines, without advancing prices materially. At the same time, there is no disposition to traffic in the speculative mines, although some of them are undoubtedly very cheap at the prices at which they are offered for sale. Ingot copper holds firm at 15⅛@15¼c., and there are indications that higher prices will prevail during the ensuing fall and winter. Should this be the case, we shall, no doubt, have a more active market for all the copper stocks, and more active prices. Calumet & Hecla advanced from $240@$243 on small sales, with no stock offered to-day at less than $245. Franklin was also better, with sales at $9⅞@$10. The August product was 188 tons, a slight increase over the corresponding month of last year. Quincy continues in good demand, with sales at $46, which is also bid, none offered. A gain of 57 tons in the product for August, compared with last year, is reported, and the mine continues to look well. Osceola sold at $18, and Atlantic at $10, same as last week. Huron sold at $1 9-16 (100 shares only), the same being bid. This mine doubled its production in August, as compared with last year, and looks cheap at the price at which it is selling. Pewabic sold at $3. The product for August shows a falling off of about 15 tons from last year.

In silver stocks, there is but little doing, and prices show no material change. Bonanza sold at $1¼. Catalpa, 87½c. Sullivan, 87½c. Harshaw, 50c. Silver Islet, $3⅛@$3, and offered at the latter figure.

At the Boston Mining and Stock Exchange, there was no special feature. Prices for the stocks dealt in show but little change, and there is not much margin for operations. Bowman Silver steady at 17@18c. Massachusetts & New Mexico, 4@5c. Empire, 17c. bid. Dunkin, 29@30c. Sullivan is more active and in fair demand at 87½@92½c.; sales at the latter price, buyer 30.

3 P.M.—At the Board this afternoon, Huron sold at $1⅛, and closed $1¾ bid, $2 asked. Silver Islet sold at $3, closing $2¾ bid. Sullivan, $⅞@$1. Bowman Silver sold at 16c. Calumet & Hecla, $240 bid and $245 asked. Osceola, $17½@$20. Quincy, $46½@$47¼. Franklin, $10. National, $1.

Corresponding period last year	2,579,027

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 4 per cent. During the week, the bank gained £107,000 bullion, and the proportion of its reserve to its liabilities was raised from 47 9-16 to 47 11-16 per cent, against 39¼ per cent at this date a year ago. September 6th, the bank gained £50,000 bullion on balance. The weekly statement of the Bank of France shows losses of 380,000 francs gold and 1,076,000 francs silver.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of July.	Year from Jan. 1st, 1883.

Silver "	237,020	— 915,320

METALS.

NEW YORK, Friday Evening, Sept. 7.

Copper.—There have been sales during the week of about 200,000 pounds at 18⅛@18¼c., the latter for wire bars, and 18¼c. is now quite freely insisted upon. A better feeling prevails generally, and in other brands than Lake, slightly higher figures have been realized. We quote 14⅛@14⅝c., according to brand.

England is lower, cabling £69 for Best Selected and £63 7s. 6d. for Chili Bars.

Tin.—A fair business has been done during the week, and prices here keep up well in spite of weaker markets in London, whence cables come showing £94. Singapore, on the other hand, is higher, parity £95 15s., a rise due to the buying of Chinese parties in that market in anticipation of war with France, growing out of the Annam troubles. Here Straits is quoted 21⅛c. spot cash; Australian, 21⅛c.; Billiton, 21¾; and Banca, 21⅛c.

Lead.—Holders are stiffening, and have advanced their asking price from 4·30c. to 4·35c. It would be a difficult matter to secure any round lots for less at the present time. On the other hand, however, any attempt to put a good-sized lot on the market would be impossible without making concessions. The course of the market in the near future will largely depend upon whether holders maintain an unbroken front.

From St. Louis, Messrs. John Wahl & Co. wire us as follows:

There is a somewhat better feeling, due to growing inquiry. The market is very steady at some advances on last week's quotation, with a good demand for refined lead. We note sales of 130 tons of Hard lead at 4·05c., and quote Refined 4·10c. Our receipts are 1000 tons this week, the same as last week.

Messrs. Everett & Post, of Chicago, telegraph:

Our market is strong and the demand good. Buyers are taking lead liberally. We quote nominally 4·12½@4·15c.

Spelter.—The flooding of a number of mines in the Joplin District has made ore scarcer and dearer; and on the other hand, the low prices have caused the closing down of works. There have been sales during the week at 4⅛c., which we quote. England cables unchanged, £15 for Silesian.

We call the attention of those interested in spelter to the admirable paper of Mr. F. L. Clerc, the first installment of which we print elsewhere.

Antimony.—This metal is quiet and dull.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Sept. 7.

According to the figures published in a supplement of the New York Metal Exchange, the total stocks in bond in the ports of New York, Philadelphia, Boston, Baltimore, and New Orleans were as follows:

	Sept. 1, 1882. Tons.	Jan. 1, 1883. Tons.	Aug. 1, 1883. Tons.	Sept 1, 1883. Tons.
Pig-iron	6,927	6,330	3,735	2,261
Spiegel iron	1,514	4,131	1,426	467
Old rails	15,396	5,504	2,204	171
Scrap iron	585	1,384	3,147	157
Scrap steel	718	456	306	306
New iron rails	7,450	6,642	376	355
New steel rails	3,008	4,816	....	121
Grand total	35,598	29,263	11,194	11,818
Increase during August, 1883				624
Decrease during 12 months				23,780

American Pig.—September thus far has been a severe disappointment. There is no use in denying that the evidences of an improvement in August, which were so carefully nursed and were made so much of, have again disappeared. It is true that many furnaces are out of blast, and yet it is true also that the production is still ahead of the requirements. The excess, it is true, is not great, but still there is an excess, so that even No. 1, which for a while was scarce, can now be obtained without difficulty. There is not much shading of prices, however, chiefly for the reason that it is not believed that lower figures would tempt buyers. The fact is, that consumption is very much narrowed down. Eastern consumers who supply the mills with machinery and castings are doing very little business. The great car manufacturing establishments and the many other works which supply the railroads are doing comparatively little. The stove trade is only moderately active, and the only branch in which there is unusual activity is the pipe-makers, who are as busy as they can be, and are behind in their orders. This is not a glowing picture, but we believe that it closely reflects the condition of the trade.

Mr. Edward J. Shriver, Secretary of the Metal Exchange, has the following returns from 91 furnaces:

	No. 1.	No. 2.	Bessemer Forge and lower grades.	Grade not specified.	Total.
Stocks Aug. 1	14,738	21,998	44,014	4,468	85,218
" Sept. 1	14,852	20,891	36,913	5,329	77,985
Production in July	8,105	5,655	8,762	5,452	27,974
" " Aug.	7,798	3,947	4,400	7,218	23,363

These figures are encouraging so far as the supply is concerned, but they do not invalidate the above statement, which is based upon the shrinkage of the demand.

Transactions during the week have been on a moderate scale. We quote No. 1 Foundry, $21.50@$23; No. 2, $19@$21, according to quality; and Gray Forge, $18.25@$19.50, all at tide-water. Bessemer Pig is lifeless, and Spiegeleisen is quiet at $30.50@$30.75 for 20 per cent, at which figure a 1000-ton lot changed hands. Lower grades are dull at $25@$25.50.

At the Exchange, the following sales were reported: Saturday, 200 tons No. 1, January, $22.25; Monday, 300 tons No. 1, December, $22; Thursday, 200 tons No. 1, December, $21.87½, and 200 tons No. 1, January, $22; and to-day, 500 tons No. 1 at $22.25.

Scotch Pig.—Though the arrivals have been moderate, a considerable portion has gone into store, an indication of the fact that it is difficult to place the metal at current figures, which are still quite firmly adhered to. Freights are cabled lower, 4s. 6d. from Glasgow.

We quote ex ship: Coltness, $23.50@$24; Langloan, $23@$24; Summerlee, $23; Dallmellington, $21@$21.50; Eglinton, $20.50@$21; and Glengarnock, $22.50@$23.

At the Exchange, the following slightly lower cable quotations were received: Coltness, 60s.; Langloan, 59s.; Summerlee, 56s. 6d.; Gartsherrie, 56s. 6d.; Glengarnock, at Ardrossan, 55s.; and Eglinton, at Ardrossan, 48s. 6d. Warrants to-day were 46s. 5d.

Steel Rails.—Very little business has been done, outside of small lots, of which some were placed for prompt delivery at $37.50 at mill, which is equal to about $39 at tide. In the pending large orders, nothing has been done, buyers' and sellers' views being too far apart.

Old Rails.—There have been sales of some small lots at better figures, and $23.50@$24 is now asked for Ts.

Scrap Iron.—Very little has been done, quotations remaining $23.50 ex ship.

Philadelphia. September 7.

There is a tendency to better prices in iron and steel. A number of large buyers have purchased for from thirty to sixty days' requirements. Lowest prices have been reached.

Digitized by Google

Pig-Iron.—Special brands have been moving rather more freely during the past few days at $22.50@$23.50. Sales of about 2000 tons of Standards in 50 to 100-ton lots were heard of at $22@$22.50. Some movement in inferior No. 1 is reported at $21.50. No. 2 continues dull, but some business was closed at $19.50@$20. Two or three makes are still held at $21. More activity may be reported in mill irons at $19@$20 delivered, and a fair amount of business is now about to be closed at about $19. Some inquiries are for 1000-ton lots. Dealers in Scotch report more business for the week, but prices lower. Bessemer can not be moved at tide-water rates, $21.

Charcoal Blooms are worth $57.50 and anthracite $10 less.

Muck Bars.—Bars range from $33.50 to $35 asked.

Merchant Iron.—Only a quiet steady demand is reported at 2·15@2·20c. for Refined, and 2@2·10c. for not first-class. Local mills are working full-time, but with very little business for October, hence prices can not be regarded firm. Western iron is coming this way at from 2@2·10c., and has a disquieting effect, mainly in preventing large transactions. Skelp is not active, though negotiations are pending for large lots.

Plate and Tank.—The favorable situation continues, and large and small transactions are frequent at 2·35@2·50c. for Boat and Tank iron; 3c. for Shell iron; 4@4¼c. for Flange; and 5@5½c. for Fire-Box. Requirements which were withheld during August are now coming forward.

Structural Iron.—A few orders were placed for small lots, early delivery, at 2·40@2½c. for Angles; 2·75c. for Tees; 3½c. for Beams and Channels.

Sheet-Iron.—The sheet-mills are securing their full share of business at card rates, being 4@4½c. for Common. Galvanized deliveries for building requirements are large.

Wrought Pipes and Tubes.—Two or three inquiries are on hand this week for large requirements. The local establishments are busy. Boiler tubes are generally quoted 60 off, and gas and steam pipe 70@75, according to order.

Steel Rails.—Small business is coming along. Large orders are likely to be placed any time; but, for unexplained reasons, there is a delay. Quotations for winter delivery $37@$37.50; fall, $38@$38.50; light sections, $40@$41.

Old Material.—Offers at $24 by sellers for large lots. Bids at $23. Double Heads held at $26. No orders.

Scrap.—Cargo nominally $23.50. Yard No. 1, $24@$25. Nothing worthy of note doing.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Sept. 7.

Anthracite.

The situation has not materially changed since our last report. Coal continues abundant, and as the few buyers there are are cautious, there is a constant pressure to move a surplus. That there can be no real improvement in the prices so long as such a condition of affairs lasts, will be patent to any one. The fact, too, that dealers are largely supplied and are expecting considerable coal still to be delivered, does not encourage the belief that the trade will witness the usual fall activity. The news from the iron trade is discouraging, and from Eastern manufacturing centers the frequently repeated tale of dullness is repeated. The early future must decide whether it will be possible to continue full work during the rest of the year. Two of the companies will probably, from special reasons—on account of heavy deliveries, or the facilities offered for pushing coal Westward—resist any such change in the programme; but there is little doubt that they too will feel the pressure as soon as the markets begin to contract with the beginning of winter.

The Western Association will meet in Chicago next week, with the object of patching up some of the differences there. How far the attempt to keep the trade in order will be successful, remains to be seen.

Bituminous.

There is a very sharp competition for what little trade there is, and cutting is apparently indulged in quite liberally.

STATISTICS OF COAL PRODUCTION.

Comparative statement of the production of anthracite coal for the week ended September 1st, and year from January 1st:

TONS OF 2240 LBS.	1883. Week.	1883. Year.	1882. Week.	1882. Year.
Wyoming Region.				
D. & H. Canal Co.	104,005	2,533,162	55,187	2,235,321
D. L. & W. RR. Co.	129,058	3,199,182	78,501	2,930,636

Total	778,597	20,391,354	377,504	18,440,500
Increase		1,950,854		
Decrease				

* Included in tonnage of the Philadelphia & Reading Railroad. † Reports have not been received.

The above table does not include the amount of coal consumed and sold at the mines, which is about six per cent of the whole production.

Total same time in 1878		10,737,415 tons.
" " " 1879		16,972,754 "
" " " 1880		14,216,454 "
" " " 1881		18,033,921 "

The increase in shipments of Cumberland Coal over the Cumberland Branch and Cumberland & Pennsylvania railroads amounts to 594,558 tons, as compared with the corresponding period in 1882.

Belvidere-Delaware Railroad Report for the week ended September 1st:

	Week.	Year. 1883.	Year. 1882.
Coal for shipment at Coal Port (Trenton)	2,926	75,716	58,748
Coal for shipment at South Amboy	16,148	516,363	558,332
Coal for distribution	18,097	523,063	470,810
Coal for company's use	2,325	103,627	84,422
Total	39,496	1,218,761	1,172,312
Increase		46,457	
Decrease			

The Production of Bituminous Coal for the week ended August 25th was as follows:

Tons of 2000 lbs., unless otherwise designated.

	Week. Tons.	Year Tons
Cumberland Region, Md.		
Tons of 2240 lbs	55,742	1,550,651
Barclay Region, Pa.

THE annual meeting of the American Society of Mechanical Engineers will be held in this city on the 3d of November.

A STATEMENT has appeared in some of the newspapers in this city, to the effect that a decision has been reached in reference to Alabama coal and iron lands. Our correspondent in Washington has been unable, by personal application to the heads of departments, to verify this rumor. For some mysterious reason, which it is suspected is of a political character, all claims of the kind are now uniformly suspended.

AN interesting example of the originality which American iron-makers bring to bear upon the solution of exceptional problems is furnished by the manner in which the managers of the Lucy furnace, at Pittsburg, got over the difficulty of handling their cinder. There was no room for dumping in the vicinity of the works; and after many and expensive experiments, cars were designed which allow the cinder to be carried over long distances in a liquid condition. It is related that the cinder was thus in one winter carried a distance of forty miles, to help break up an ice-gorge, or rather melt it away—a feat which was successfully accomplished.

THERE has been much rejoicing in Silver Cliff, Colo., over what is termed the brilliant success of the Duryea process. There has been a banquet, the band has played, and toasts have been drunk, and Silver Cliff's citizens are reported to be at "fever-heat," though it is not stated whether the toasts did it. We regret that in their excitement the Silver Cliffians have not as yet submitted any very intelligent account of what was done at the furnace, and how it was done. We are inclined to believe, however, from stray data in the columns of our Colorado contemporaries, that the process has undergone some modification since the time we last heard of it. It seems that the silver is not converted into a vapor which is leisurely condensed, but that "slag and molten lead pass automatically from the cylinder into the sump." We await the publication of a full record of work without "fever-heat," and trust that we may soon be able to place the result before our readers.

MINERALOGY and geology are sciences with which a mining engineer strives to familiarize himself. Many of those eminent self-made mining engineers who infest some of our mining camps are conscious of the fact that it impresses the average layman to hear hard words. Their efforts to talk wisely would be amusing if they were not occasionally dangerous. The latest example of an unfortunate struggler with the mysteries of mineralogy is Mr. F. P. THOMPSON, M.E., of Monterey, who, as he tells the world in a report on the Minas Viejas of Villaldama, Nuevo Leon, Mexico, has "followed the avocation of mining during a quarter of a century." If he has, he has learned nothing worth knowing since he began. According to our authority, who may be able to wield a pick well enough, the country-rock of the Villaldama District is granite and the dike "siliceous limestone or quartzite." The copper ores are "sulphate and carbonate, and nearly all of them silver-bearing. Some of the latter contain so large an amount of gold that they become in fact a gold ore, with which copper is only associated. These characteristics will probably continue until water-level is reached, when the ore will become a sulphate and be much richer, assuming the character of 'brognordite'—a complex compound of antimony, arsenic, sulphur, lead, and silver, which yields readily to the lixiviation process." The so-called "brognordite" carries from 46 to 48 per cent of lead. We advise Mr. THOMPSON to stop writing. He is weak on mineralogy, geology, and metallurgy. Unfortunately, he is a type of a class to whom we respectfully but earnestly tender the same advice.

MR. JOHN JARRETT, ex-President of the Amalgamated Iron and Steel Association, recently testified before the Senate Committee on Education and Labor, whose members, by the way, have been forced to listen to an endless gush of bosh. Mr. JARRETT is conceded to be a clear-headed, intelligent man, of much executive ability, and his utterances on the subject of the condition of the miners and iron-workers, if not accepted as conclusive evidence, are at least listened to with respect. Mr. JARRETT is quoted as saying, concerning the miners: "In consequence of their utter demoralization, they spend at least one half of their earnings in drink." That the latter is, unfortunately, one of the most serious circumstances connected with our mining population, there can be no doubt whatever. The appeals constantly made by their own mates, in the labor journals, to the body of the miners, furnish confirmatory evidence of the fact. We believe, however, that Mr. JARRETT is slightly mixing up cause and effect. A man "demoralized" by lack of work or poor pay does easily take to drinking; but the trouble is generally brought about in just the other way. The men have the bad habit, are shiftless, lazy, apt to jump at the first opportunity to pose as the martyrs of "grinding monopoly," etc. The leaders of the miners' organizations recognize the evil, and yet their efforts, based as they are upon a mistaken notion of the "dignity of labor," are misdirected. We do not want them to become temperance apostles, because that would not do any good; but they could do much toward diverting the occupations of the men in their leisure hours into better channels. They would, in the end, accomplish more real good than by going about preaching strikes, or persecuting "scabs," as they occasionally do. Their main work, of course, is to organize, and to further such methods as arbitration, which is entirely proper and right. But they only too frequently agitate in the manner indicated, while they ought to be at work creating reading-rooms and providing popular lectures and other means of instruction and diversion.

THE NEW ENGLISH PATENT LAW.

After much discussion and quite extensive modification, the new English patent bill has become a law. Its provisions will be closely scanned by Americans, because in no country outside of their own are the rights conferred upon inventors by the patent laws so valuable as in Great Britain. In many leading industries, the race between British and Ameri-

Digitized by Google

can specialists is very close, and improvements brought out on either side of the Atlantic are eagerly watched on the other. The liberality of our own patent laws has favored English inventors, while the provisions in England have checked a corresponding utilization of American inventions there. The new law enacted in Great Britain begins to approach our own in at least one important particular, that of reducing the fees. Briefly, the system adopted is the following: An inventor must send to the patent-office a provisional specification, and, on applying for provisional protection, pays a fee which has been reduced from £5 to £1. The application passes the scrutiny of an examiner, who decides whether or not the specification fairly describes the invention, whether its title sufficiently indicates its object, and whether the application conflicts with any other unsealed application. Appeals from this examiner's decisions go to the law officers of the department. The applications may be made directly to the office by post, without the intermediacy of an agent; but certain provisions in the new law make such a case dangerous, and the experience of most inventors in this country with our liberal office has been such as to generally discourage any such attempts at saving the agent's fees. When the provisional specification has been approved—remaining secret until that time—the inventor must prepare his final specification within a period of nine months from the date of application. It is again passed upon by the examiner, and then is open to public inspection, and is sealed when passed by the comptroller. The government fees for completing the patent for the first term of four years are £3 now, instead of £20 formerly. There is no alteration in the amount of the subsequent payments for the extension of patents from the first term of four to fourteen years; but in place of paying the £50 and £100 in lump sums at the end of the third and seventh years, these amounts are payable under the old law at the option of the patentee, either in one sum of £50 at the end of the fourth and £100 at the end of the eighth year, or by annual payments of £10 before the end of the fourth, fifth, sixth, and seventh years, £15 before the end of the eighth and ninth years, and £20 before the end of the tenth, eleventh, twelfth, and thirteenth years. The English patent-office has therefore made a compromise between its old system and that in force in this country. It has justly made it easy for the poorest to obtain protection for his invention, but still exacts a tribute from a patentee when he presumably has had ample opportunity to gather some slight return from it. A patent that has not shown vitality enough during a period of four years of freedom from payments to survive an annual expenditure of £10 deserves to lapse. We have too many idle patents waiting until some one else will make room for the invention, in order to force a round price for an investment of one hundred dollars, more or less, in a "bright idea." Thus far, the provisions of the new English patent law will, on the whole, meet with the approval of thinking inventors and manufacturers.

There is, however, a very vicious clause, awkwardly framed, which we fear may be used by unscrupulous persons, particularly to the prejudice of foreign inventors. It reads: "If, on the petition of any person interested, it is proved to the Board of Trade that, by reason of the default of a patentee to grant licenses on reasonable terms, (*a*) the patent is not being worked in the United Kingdom; or (*b*) the reasonable requirements of the public with respect to the invention can not be supplied; or (*c*) any person is prevented from working or using to the best advantage an invention of which he is possessed, the Board may order the patentee to grant licenses on such terms as to the amount of royalties, security for payment, or otherwise, as the Board, having regard to the nature of the invention and the circumstances of the case, may deem just, and any such order may be enforced by mandamus."

The object of this clause is too evidently that of preventing a misuse of the exclusive rights granted to inventors by patentees. It may be intended to meet such contingencies as the refusal of a foreign inventor to allow English manufacturers to enjoy the benefits of an improvement, or of an English inventor to moderate real or imaginary extortionate claims for compensation. It may be the desire to guard against high prices of patented articles by keeping the supply limited, or may be proposed to check any attempts to block progress by withholding the use of prior patents. We have in this country repeatedly felt and, in some industries, are still suffering under the evils to which such abuses of the rights of patentees occasionally lead. But still we do not believe that compulsory licensing in the form proposed by the new English law would commend itself to any one. The provision is framed so indefinitely that it is difficult to understand how it could pass the scrutiny of legislators or the public and the press, without the most vigorous protests. It puts a power into the hands of unscrupulous or influential manufacturers against poor inventors, which will probably be wielded in more than one case to browbeat the latter. It leaves it in the hands of government officials to decide what are "reasonable terms" for licensing. In England, as well as elsewhere in the world, government officials are generally the very last to whom such questions should be submitted for decision, because the fact that they are not in daily contact with the business community renders them unfit for it. It is to be sincerely regretted that the new English patent law is marred by such provisions, which, we repeat, will be particularly dangerous to foreign patentees, because the sympathies of judge and jury in cases coming under it will be against them.

THE POSITION OF LEAD.

The course of the lead markets should be closely watched by the majority of miners, particularly in Colorado and Utah, because its fluctuations largely affect the returns for ores shipped to smelters. Like every other metal produced in this country, though in a less marked degree, lead has almost constantly declined since the beginning of the present year, as the following summary of the prices will clearly show:

PRICES OF LEAD IN NEW YORK IN 1883.

	Range.	Average.
January	4·50 @ 4·70 cents.	4·65 cents.
February	4·50 @ 4·60 "	4·55 "
March	4·50 @ 4·65 "	4·55 "
April	4·40 @ 4·62 "	4·50 "
May	4·30 @ 4·55 "	4·40 "
June	4·40 @ 4·45 "	4·40 "
July	4·30 @ 4·40 "	4·32 "
August	4·20 @ 4·30 "	4·25 "

On the whole, the market in this city has shown less buoyancy than that in the West, where consumption has been going on at a less slackened pace than in the East, particularly for corroding purposes. The result is, that the views of those interested in the metal on the Atlantic coast are liable to be tinged with a less hopeful tone, while on the other hand, we fear that the confidence of producers in the West is not quite warranted by the situation. It will be well to look the matter squarely in the face. Two facts, we believe, will be generally conceded: consumption throughout the country, East and West, has not, thus far, been as large as it was last year; while production has been heavier than ever before. The result has been an accumulation of stock which some have estimated as high as from 20,000 to 25,000 net tons. It is probable that this guess is not very far from the truth. One point, however, must be considered in connection with this stock, which somewhat modifies the force with which those who argue from its existence point to it. As usual, consumers have bought sparingly on a falling market, particularly as they, like all prudent business men during the current year, have shrunk from adding unnecessarily to their engagements. We believe, therefore, that an inventory of the manufacturers throughout the country, if made now, would show a marked decline in the stock of raw material held by them. The producers and their agents have been carrying more than their usual share of the surplus. It is concentrated in the hands of a few parties, who have recently by their firm attitude stayed the gradual decline of the metal. Consumers, on the other hand, convinced that holders must weaken under a load to which they must add constantly to sustain their position, are obstinately buying only to cover pressing needs. The representatives of the three or four works which are carrying the stocks, however, look forward to the time when the exhaustion of supplies of raw material will force buyers to enter the market for large lots. Much depends on the activity of the demand for shot and the inquiry for building purposes. Should the fall trade prove a disappointment, manufacturers will have no trouble in supplying themselves through those producers who, under the circumstances, believe in the policy of selling lead as fast as they make it. Their number and the capacity of their works are, we believe, rather in the majority, and therefore it is likely that the present deadlock, with its stiff nominal prices, may continue for quite a long period. There is also the danger that, should the candle be held too high, one or two more of those who are carrying heavy stocks will unload on the market, leaving the others to bear their burden as best they may. Unless the consumption increases considerably, lead can not ultimately resist the pressure because production is going on unabated. For weeks and possibly for months to come, it will hold its own, or may even be pegged up; but this steadiness should not deceive producers as to the dangers with which the metal is beset.

This fact should be borne in mind: There is no scarcity of lead, no exceptional consumption to warrant even current figures, but the metal is artificially sustained. In common with all producing interests, we hope that an expansion of consumption will warrant the prices now asked. They are fairly remunerative to the makers in the different sections of the country. The latter, however, should be prepared to meet every contingency, and do all within their power to reduce the cost of production. The present period of uncertainty will certainly enable buyers of ores to dispose of the purchased metal without a steady loss, which they must suffer on a constantly declining market. According to their view of the future of business in general, miners, we presume, will show an inclination to make long contracts if they are pessimists, or hold back if they are sanguine. Weighing all the evidence which has come under our observation, we are inclined to believe that little is to be gained by the latter course.

The Early Discovery of Tin in the Black Hills.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In your "Correspondence" column of August 25th, "Glück Auf," writing from the Black Hills, speaks of the recent discovery there of tin in paying quantities. In view of the importance which attaches to the discovery of valuable tin ore in the United States, it may be of interest to relate how, as far back as 1876 or 1877, Mr. Richard Pearce, of the Boston & Colorado Smelting Company, then at Black Hawk, Colorado, discovered tin which came from the Black Hills country. A prospector, sending ore-samples from that section to the Boston & Colorado Smelting Company for assay, unable to secure currency, sent gold-dust in payment. Examining the gold-dust, Mr. Pearce found some black grains, which proved not to be magnetic iron, as might have been expected, but tin oxide. Interested, of course, he sent at once to the prospector for samples of the black sand from which the gold-dust of his section was obtained. The samples which were received contained high percentages of tin oxide; but the region was then much more difficult of access than at present, and investigation was carried no farther. It is to be hoped, however, that the improved transportation facilities for the Black Hills, now that both vein ore and placer deposits of tin have been discovered, may warrant the investment of capital, and at no distant day result in the profitable production of tin in the United States. J.

DENVER, COLO., Sept. 5.

Granulite in Canada.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: The article in last week's ENGINEERING AND MINING JOURNAL on the subject of Glass from Granulite by the Siemens process is one which is very interesting. I had occasion, a few months ago, to inquire fully into the subject while in London; and one of the directors sent a specimen of a railroad tie out here, which is now in Philadelphia. The purpose then was to sell the patent for America, or to obtain orders. The latter was found impossible, the answer given by the railroad companies being, that in a country like America, where timber was plentiful, there was no advantage in adopting glass ties. Then, with regard to the patent, the first thing necessary was to find the quality of mineral suitable for the purpose. To obtain this, I went into Canada last June, and pitched my tent on the various islands situate on the inland lakes, conveniently placed for cheap and easy transit. The result of my travel, extending over one hundred miles, was the discovery of immense deposits of suitable granulite; also beautiful pink granite, relieved by the presence of mica and feldspar, making a magnificent stone for building purposes. I also met with virgin iron lodes, and one copper lode. A great part of the country through which I passed abounded in phosphate of lime, as well as limestone, to say nothing of the enormous deposits of red and yellow sandstones.

Doubtless some of your readers have prospected the banks of the Hudson, as well as the Adirondacks. If so, I should like to know something of the strata. I am sir, yours obediently, T. B. ALDERSON,

NEW YORK, Sept. 8. Mem. Inst. M.E. Eng.

Bessmerizing Copper Matte.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In your issue of July 7th, I note a letter from Dr. Percy, the eminent English metallurgist, which I can not allow to pass without a reply. I regret that Dr. Percy did not take the trouble to read my English patent. He would have recognized that my process of treating copper ores differs essentially from the one patented in 1856 by Mr. Keates.

I need not call attention to the fact that if Mr. Keates had really discovered in 1856 a more economical and truly industrial process, he would certainly have applied it since on a large scale in the Swansea or Liverpool copper-works. This has not been done—not even, I may venture to say, in the works belonging to the inventor.

Besides this, Dr. Percy himself, who has since published a treatise on the metallurgy of copper, does not say a word on this method, which he would not have failed to allude to if it had produced results.

I have stated in the foregoing, and I will show, that my process differs completely from the one to which Dr. Percy points. My process is based on doing away with coal for the purpose of producing the necessary temperature, which is solely generated by the intermolecular combustion of the iron, the sulphur, and the other metals which are more readily oxidized than the copper in the matte. Is there any thing similar in the description in the Keates patent? None; on the contrary, the specification calls for a heated reverberatory in which the operation is carried out. Consequently, the use of fuel is necessary. It is distinctly stated, in the description, that it is necessary to raise the temperature of the furnace, in order that the matte may remain in a state of complete fusion during the action of the blast.

The intermolecular combustion to which reference is made in the above, and which is the foundation of my process, has led me to design a special apparatus which does not resemble the reverberatory furnace described in the Keates patent. I believe that these explanations will suffice to make the subject clear to your readers. PIERRE MANHÈS.

LYONS, FRANCE.

A RECENT bulletin of the Census Bureau is that giving a partial estimate of the consumption of forest products as fuel. It appears that 32,375,074 persons use wood for domestic purposes. Illinois consumed during the census year 5,200,104 cords, value, $14,136,662; Indiana, 7,059,874 cords, value, $18,334,729; Iowa, 5,090,649 cords, value, $14,611,280; Minnesota, 1,669,568 cords, value, $5,873,421; Michigan, 7,838,904 cords, value, $18,197,249; Wisconsin, 7,207,126 cords, value, $11,863,739; Dakota, 422,948 cords, value, $3,028,300; Montana, 119,947 cords, value, $460,688.

THE DISCOVERY OF TIN-STONE IN THE BLACK HILLS OF DAKOTA.

Written for the Engineering and Mining Journal by William P. Blake, F.G.S.

(*Concluded from page* 146.)

QUANTITY OF THE TIN ORE.

The extent and quantity of the greisen rock and the percentage of tin-stone in it are the two most important questions in an economical and mining point of view. As regards the first, the chief evidence, at present, is in the outcrops or exposures at the surface. These are extensive and decidedly encouraging. Without regarding the possible occurrence of massive ore in bunches, and confining the estimate to the greisen rock alone, it may be said to crop at intervals over a length of 100 feet by from 70 to 100 in breadth. These outcrops are irregular in form, and vary from two feet to twenty feet, or more, in width. There are four chief outcrops, all showing tin ore. Very little work has yet been done to open up these outcrops of greisen. An open cut some twenty-five feet long and about fifteen feet deep at the face is the largest excavation. It cuts through the pit which was sunk at first for mica, and followed the heavy black ore downward. In cutting this opening, a considerable quantity of the greisen rock has been blasted out, showing specks and grains of tin ore throughout its substance. This greisen should be regarded as the chief and most reliable ore, though no doubt many masses and branches of the massive cassiterite will be developed, apart from the greisen when the ground is opened. The greisen is favorably placed for cheap mining: the surface of the hill slopes off from it each way, permitting it to be attacked by cuts or open quarry in several directions. It is easily drilled for blasting, and the most effective and economical method of getting it out, in quantity, will be to work it in open quarry, putting in heavy blasts, and then cracking up the large blocks by smaller holes, letting the fragments roll to the base of the hill, where, by means of a suitable barrier of pine logs, forming a rude ore-bin, they may accumulate and be delivered as needed through chutes into cars below, thus avoiding the expense of lifting and handling. The cars should then deposit the rock at the top of a mill, so arranged that the ore need not be again handled or lifted until the concentration is complete.

The greisen rock can be crushed with great ease, either under stamps or by rolls. The tin ore separates easily from the mica and spar, and, after crushing, can be washed out by the ordinary methods of panning or concentration. This was demonstrated by many trials in panning. There is very little loss. The ore settles to the bottom, and deports itself very much as gold does in panning out. The ordinary concentrating apparatus will handle the tin-stone effectively. Water is abundant at all seasons, except probably for a time in the depth of winter, when the snows do not melt fast enough to fill the rivulets.

On reaching the mill, the broken rock should pass over coarse grates, in order to separate the heavy blocks from the medium-sized masses. There should be three rock-breakers; one of unusual size, to receive masses of rock from 15 to 24 inches in diameter, and the others to take the product of the first breaker together with the other masses that are suitable for a 15 by 9 breaker. The two 15 by 9 breakers should be arranged to have automatic feeding, which can be easily secured, and would effect a great saving. The crushed ore can then be passed through rolls, or directly to the stamps. If stamps are used, the grates should be coarser than for gold quartz, and slotted punched screens will no doubt deliver the mica much freer than woven wire screens, or screens punched with round holes.

PERCENTAGE OF TIN-STONE.

Ordinary hand samples of the greisen, taken from the large masses broken from the open cut, and rejecting the richer portions, will yield from 6 to 10 per cent of clean tin-stone, or black tin, of high grade. Some masses will yield from 10 to 50 per cent by weight; but the general run of the ore is about 6 per cent, excluding the poorer portions. The general average of samples broken from all parts of the outcrops at the surface is about 3 per cent. It is certain that there will be no difficulty, when the ground is opened by blasting, in selecting the rock so that an average of at least 3 per cent can be maintained, if this limit shall be found desirable. But it is probable that rock containing only 1 per cent may be profitably worked if the mill is properly placed and equipped.

The percentage of tin-stone, or black tin, in the greisen, it will be seen, compares favorably with the percentage of tin-stone in the ores of other and well-known tin regions. In Cornwall, for example, where the statistics of tin mining and smelting are carefully kept under the direction of the government, it is found that the average percentage of black tin in the whole mass of tin ore as mined and stamped, or prepared for dressing, is not over 45 pounds to the ton, or 2 per cent. So, also, at Altenberg, Saxony, the smelting ore, or black tin, is 2 per cent of the whole mass. But a much lower percentage than this has been worked. According to Phillips and Darlington, it did not exceed 17½ pounds of black tin to the ton at one of the largest mines in West Cornwall in 1855; this being equivalent to 0·86 per cent. The same authority, in describing the effectiveness of the ordinary stamp-mill in crushing tin ores, gives the following figures: The average number of stamps in use at the Polberro mines was 70, and the number of tons crushed in the course of five years was 106,249 tons. This quantity averaged 20$\frac{1}{10}$ pounds, or 0·89 per cent of merchantable black tin per ton. The profit per stamp amounted to £210 for the whole period, or £42 per stamp per annum.

STREAM-TIN.

Stream-tin, or alluvial tin ore derived from the disintegration of the veins and rocks, occurs here as in all important tin regions, and it promises to play an important part in the future development of the region.

It is found, as might be expected, in the water-courses which head at and near the Etta claim on Tin Mountain, and in other places, thus giving good evidence of the existence of other veins and resources than those on Tin Mountain. On Battle Creek, between the Etta location and Harney City, in sluicing for gold, a large quantity of heavy black mineral in grains from the size of peas to the magnitude of pigeon-eggs and larger are abundant. This heavy black ore has always been a hinderance to the placer miners on that stream, and has been thrown away as useless. I

Digitized by Google

find it to consist largely of tin ore of good quality; some of it shows small adherent scales of mica, indicative of its derivation from greisen.

It is not easy to reach the bed-rock along this creek, owing to the abundant supply of water and the deficient drainage, without a bed-rock flume, which has been proposed by the gold miners for the gold alone. It is now probable that both the stream-tin and the gold will be mined together, and to much greater advantage than if worked alone. Prospecting for stream-tin along the valley of this stream is still in progress.

The ore has been found also on Iron Creek, and later on Spring Creek, ten miles or more north of Tin Mountain. This last is comparatively free from fragments of a heavy black mineral, apparently wolfram, which accompanies all the stream-tin ore yet found, but which is harder than wolfram and has a lower specific gravity (h. 6; sp. gr. 6·1 to 6·7). Several species are probably represented in the alluvial concentrations; but there is a notable absence of magnetite, of hematite, and of chromite.

The evidences, so far, go to show that there is an extensive region of deposits of stream-tin, and that tin ore must occur at many distant points in abundance; and in the case of mining it, it must hold a relation to the parent sources similar to that of placer gold to the gold in veins. In alluvial tin mining, the production per hand per day must depend, of course, chiefly upon the abundance of the ore and the depth of gravel and clay under which it lies. The "*pitting-off*," or removal of the top stuff, is the chief item of cost. The same methods and economies of working practiced in alluvial gold mining are applicable here also. The rockers, toms, and sluices, as well as the hydraulic and drifting methods, are all available. Water and fall, or grade, are essential. The bulk and quantity by weight are, of course, very much greater than in the case of gold, and some modifications of riffles and sluices are required. The work is not so delicate, and may be more roughly and rapidly carried on than it can be when gold is to be saved.

The larger part of the tin of commerce is obtained from stream-tin. In Cornwall, at first, the tin ore was obtained solely from the alluvions of the tin region; and even as late as 1876, it is reported that 800 persons were engaged in mining for stream-tin on Red River. A considerable amount of ore is yet obtained from stream-deposits rather than from veins; and at the present time, the great production of New South Wales is from alluvial tin ores, such as were shown in profusion at the Centennial Exhibition, and again at Paris in 1878.

According to Professor Liversidge, the tin-bearing area in New South Wales is estimated at 8500 square miles. The production up to 1882 was 62,268 tons, valued at £4,339,461. The ore occurs in veins and as stream-tin. The veins traverse granite, and are considered to be like those of Cornwall. The ore is found, also, in veins of greisen, and in granulite or eurite. Sometimes the ore is found disseminated in large and well-formed quartz crystals.

The stream-tin ore occurs in much the same manner as gold, and in drift or stream-deposits of different periods of deposition and at different levels. Two distinct sets have been recognized, the older and the newer. Some of the deposits are worked under 60 or 70 feet of basaltic capping. The older tin-stone deposits are frequently so closely cemented as to require stamping. The ore is usually obtained by sluicing or by jigging. Wolfram is not abundant.

The Banca and Billiton tin is chiefly from alluvial ore, which is mined by Chinese labor.

According to Davies, at the alluvial tin mines of Banca, a miner, with the aid of water, removes from 350 to 530 cubic feet of earth in nine hours, or by estimate 12,000 cubic feet yearly, with an average product, after smelting the black tin, of twelve hundred pounds of metallic tin. In Australia, stream-tin miners are reported to handle 10 tons of earth daily.

The Chinese miners of Banca have an ingenious and simple apparatus for prospecting the deposits before digging. It consists of an iron rod about an inch in diameter and twenty feet long, which is forced down through the upper layer of sand and clay to the bed-rock. A small conical tube at the lower end serves to catch and retain a sample of the gravel from the bed-rock, and will show the presence of tin ore if it exists in sufficient quantity. A copper tube with a steel shoe is also used to obtain samples. An apparatus of this kind would be very useful at the Black Hills, particularly in the small valleys where there is a large amount of water in the soil.

The annual production of Banca tin is about 4000 tons. In the island of Billiton, the production in 1876 was 3721 tons.

NOTES ON EXPLOSIVES FOR MINING.

Sir Frederick Abel, of Woolwich Arsenal, who ranks among the very highest European authorities on the manufacture and application of explosive compounds, has, in a presidential address before the Society of Chemical Industry, made a number of observations which can not fail to be of interest to the mining public. This address is largely historical, and naturally refers frequently to subjects coming within the domain of an ordnance officer. From the long document, we choose the following extracts:

So far as mining or blasting-powder is concerned, its production at a comparatively very low price, and the absence of any standard or test of power, contributed to maintain the manufacture in a stationary condition, except in so far as any expedients could be adopted for increasing the margin of profit of the manufacturer, until, about twelve years ago, more violent explosive agents began to enter into serious competition with it. The attention which dynamite and gun-cotton had already excited at about that time, and the recognition of the fact that blasting-powder might be economically and otherwise advantageously replaced in many kinds of mining work by explosive agents more rapid and more violent in their action, led to the invention or resuscitation of a great variety of explosive mixtures for which special advantages were claimed. The greater number of these have enjoyed a very brief and inglorious existence. On the other hand, some preparations of nitro-glycerine and gun-cotton have become so firmly established as valuable blasting agents that the manufacturers of blasting-powder have long since been taught that the days are passed when powder could maintain its supreme position as the only or even the most practically useful explosive agent for industrial purposes, and that cheapness no longer contributes an all-important feature in the advantages to be claimed for it. The miner has now become critical in regard to the quality of blasting-powder supplied to him, and this has not only led to the bestowal of greater care upon the incorporation of the ingredients, and upon their quality, but has also brought about the extensive introduction of two or three forms of blasting-powder which are very decided improvements upon the ordinary black powder sold under that name.

One of these is the extra strong mining powder (E.S.M.) manufactured by Curtis & Harvey, which, in point of care bestowed upon its introduction, has much resemblance to artillery gunpowder; and the compressed powder first brought out by Messrs. Davey & Watson and manufactured by Messrs. Hall & Son, but now also produced by other manufacturers, which is at present extensively used in mining districts, and with results very satisfactory as compared with those furnished by the old blasting-powder. The perforated cylindrical form of charge, of dimensions suitable for different-sized bore-holes, was first applied, in connection with compressed gun-cotton, about sixteen years ago, and was found to present advantages independent of the nature of the explosive agent. The compact cylindrical masses of the material are convenient to pack, transport, and handle, while the conversion of the substance into a homogeneous mass of considerable density, solid throughout, except that a fuse-hole passes through the center, considerably reduces the space which it occupies in a blast-hole. Hence the effective action of the charge is increased, partly by an increase of the space available for tamping, and partly by a concentration of the action toward the base of the hole, where it is desirable that the maximum amount of work should be performed. More than one offspring of compressed gun-cotton has been similarly applied in mining industry. . . .

Although very few of the substitutes for blasting-powder which had entered the lists against it twelve years ago and upward, and which are more or less analogous to the old black powder in their composition, survived the experimental stage, one or other explosive preparation of this class still comes to the front from time to time, its claim to originality consisting generally in the novelty of its fancy designation or in the addition, to the ordinary powder constituents or to slight modifications of them, of some ingredients possessing mysterious functions, known only to the inventor and unfathomable by the chemist. Thus, many years ago, a very crude kind of blasting-powder known as Kellow's, composed of spent tan impregnated with saltpeter and sprinkled with sulphur (with the addition of a very small proportion of potassium chlorate, in the strongest variety), was manufactured for a short time in the neighborhood of Plymouth. Its comparatively safe character received practical demonstration by the factory being twice burnt without the occurrence of an explosion. That it failed to compete with common blasting-powder, even as made twenty-five years ago, need hardly be stated. However, from time to time I have met again with my old acquaintance (though sometimes sawdust had been substituted for the tan) under a new alias, such as pyrolythe or pudrolithe, or espir powder, and each time it has been re-endowed, by the re-inventors, with properties more remarkable, in point of safety and great explosive force, than it possessed before. Now the addition of a little lampblack, and of that very original ingredient of an explosive mixture, ferrous sulphate, have imparted to it fresh features of novelty and virtue, and it appears before the world as the patent safety blasting-powder, under which name it is warranted to explode only when desired, and without the development of any noxious gases or vapors whatever.

Among the more legitimate novelties in the way of blasting-powders are those recently patented by Professor Himly, of Kiel, in which sulphur is absent, and which consist of mixtures of solid hydrocarbons, such as the paraffines, or of pitch, with saltpeter, and a proportion of potassium chlorate, crude benzol, which acts as a solvent of the hydrocarbon or pitch, being used as the means of mixing it intimately with the oxidizing agents. Facility and safety of manufacture, freedom from hygroscopic properties, and superiority in point of force, are among the chief advantages claimed for these preparations, and there appears good reason why these should be realized, while, with the adoption of efficient arrangements for the recovery of the solvent, their economical manufacture should not present any practical difficulties. It may be interesting to refer to the fact that, about twenty years ago, when the subject of the improvement of time-fuses was under consideration, and their construction for use with the then new breech-loading Armstrong gun presented difficulties in respect to the fuse composition from the deteriorating action of atmospheric moisture, it occurred to me to incorporate explosive mixtures with India rubber, with the aid of benzol, whereby plastic or pliable sheets of regularly and more or less quickly burning fuse composition were obtained which were altogether free from hygroscopic properties. . . .

The circumstance that compressed gun-cotton *per se* tends, upon explosion, even in thoroughly sound and well-tamped blast-holes, to vitiate the air in underground workings and badly-ventilated places much more injuriously than nitro-glycerine preparations, on account of the somewhat considerable proportion of carbonic oxide evolved from it, constitutes one important reason why it should not find favor as a blasting agent. The same objection does not apply to compressed mixtures of finely-divided gun-cotton with the proper proportion of a nitrate, and the results of extensive experiments, made under my direction ten or twelve years ago, established the value of such preparations as mining and blasting agents. Nitrated gun-cotton, for the nitration of which barium nitrate has been selected, for reasons which I need not discuss here, finds a somewhat extensive sale now in some mining districts, and, I believe, in the colonies. As the term "nitrated gun-cotton" would scarcely have given an air of novelty to this preparation, it was introduced to the mining world some years ago under the name of tonite, and more recently under the designation potentite. . . .

Dynamite has now been so long in extensive use that its properties are familiar to all who have paid any attention to the application of explosives. In point of convenience, its plasticity gives it decided advantages over rigid cartridges, like compressed powder or gun-cotton, or tonite, on account of the greater facility of loading blast-holes with it, while, in point of power, kieselguhr dynamite, containing 75 per cent of nitro-glycerine, is, in most kinds of work, about equal to pure compressed gun-cotton. In the open air, its detonation is a little sharper than that of the latter. In experiments with long trains (continuous and spaced) of compressed gun-cotton, dry and wet, and of dynamite, which I made some

Digitized by Google

years ago, with the aid of Captain Noble's chronoscope, I found that detonation was transmitted by dry compressed gun-cotton at the rate of between 17,000 feet and 18,000 feet per second, by wet gun-cotton at between 19,300 feet and 19,900 feet per second, and by Nobel's kieselguhr (No. 1) dynamite at the rate of 20,000 feet to 24,000 feet per second. Mr. McRoberts, the talented director of the dynamite works at Ardeer, states that a ton of dynamite cartridges of the usual size (¼ inch-diameter), laid out in a line end to end, would extend one mile. According to the foregoing results, this train of cartridges would be entirely exploded in one fourth of a second if detonated at one extremity. . . .

Blasting gelatine, in its most perfect form, is translucent, of a pale yellowish color, and sufficiently firm to enable a cartridge to retain its cylindrical shape if kept lying on a flat surface. It does not soil the fingers, and the components are very difficult indeed to separate, even through the agency of a solvent of both and attempted precipitation of the nitro-cotton. Of the first sample which I received from Nobel's Explosives Company, I placed a portion in water, and have kept immersed for three and a half years. After a time, it lost its translucency—first superficially, and gradually throughout. A very small proportion of nitro-glycerine passed into solution in the water, and the mass, at the end of three years, had increased about 10 per cent in weight. Part of the sample was removed from the water, and at once placed in the cylindrical cavity of one of the leaden proof cylinders which I use for obtaining a strict comparison of the force exerted by different explosives. It was readily detonated, and, compared with a corresponding amount of a fresh sample of gelatine, the force exerted was only slightly inferior. A weighed portion of the sample exposed to the air very gradually regains its translucency in parting with the small amount of water which it has absorbed. Blasting gelatine varies somewhat in the readiness with which it is detonated. As a rule, it is not so sensitive as dynamite, but no difficulty is experienced in effecting its explosions with ordinary detonators, unless a considerably larger proportion than usual of nitro-cotton has been used in its manufacture. It is rendered extremely non-sensitive by incorporating with it a small proportion of camphor or other solid carbo-hydrogen; and this addition was contemplated by the Austrian military officials (who have adopted the gelatine for field service purposes), in order to insure its safety from explosion by the penetration of transport-wagons containing it by rifle-bullets, which in its ordinary condition it is somewhat liable to, though not nearly to the same extent as dynamite. The great proneness of the camphor mixture to escape complete explosion, even when strongly confined, led to the abandonment of this idea. The chief point needing attention in the manufacture of blasting gelatine is the character of the nitro-cotton. If the latter contain an excessive quantity of collodion-cotton on the one hand, or of trinitro-cellulose on the other, a portion of the nitro-glycerine, or rather, a liquid mixture of that substance with a very small proportion of nitro-cotton, is liable to separate after some time, and is then not unlikely to be a source of danger.

When it is remembered that two molecules of nitro-glycerine contain an atom of oxygen above the amount needed for the complete oxidation of the carbon and hydrogen, while the small proportion of nitro-cotton incorporated in the gelatine requires an additional supply of oxygen for its complete oxidation, and that the entire substance is converted into gases and vapor of water, it will be admitted, I believe, that a chemically more perfect explosive is very difficult to conceive, while, in regard to its physical properties, it certainly leaves very little to be desired. It is therefore not surprising that blasting gelatine should make rapid strides in the favor of mining communities, or that it should bid fair gradually to displace dynamite in many of its applications. In Austria, the latter appears to have been entirely superseded by it, and it is already extensively used in many other countries, while in Great Britain a temporary check in the manufacture has already been felt a serious inconvenience. The rapid and continuous growth of the dynamite industry during the past sixteen years is demonstrated by the following statement of the annual sales from factories in different parts of the world with which Mr. Nobel is associated:

	Tons.		Tons.
1867	11	1875	3,500
1868	78	1876	4,300
1869	184	1877	5,500
1870	424	1878	6,200
1871	785	1879	7,000
1872	1,350	1880	7,500
1873	2,050	1881	8,500
1874	3,120	1882	9.500

Besides the factories included in this statement, there are several others on the continent, where considerable quantities of dynamite and similar preparations are manufactured, and the patent rights in this country having expired the year before last, two or three extensive factories are entering into competition with the works at Ardeer, which, notwithstanding this, and the importations that have taken place, have been doubled in extent during the past year. A sharp line can not be drawn between the character and effects of the two great classes of mining explosives whose history I have been discussing, namely, the cleaving and displacing agents represented by the old black powder and analogous preparations, and the rending and shattering scattering the fragments to great distances. Successful results were subsequently obtained with a powder composed of saltpeter and ammonium picrate, which, under the name of picric powder, I devised thirteen years ago, for use in shells (it being prepared in France contemporaneously by M. Boutiny). This powder proved to be even somewhat less sensitive than ordinary gunpowder, and there was a tendency to some portion of the charge escaping ignition when the shell burst. The satisfactory results obtained shortly afterward with shells charged with wet gun-cotton led to the abandonment of experiments with picric powder, which is, however, about to be taken up abroad.

A substance resembling anthracite coal has been brought to Hailey, Idaho, to be tested. The specimens came from a deposit twenty feet wide at the head of Trail Creek, about twenty-three miles northeast of Hailey. The deposit lies flat, under a big sandstone reef, and can be raced on the surface for over 1500 feet. It is undergoing a thorough est; and if found to be good coal, a company will take hold of the eposit and open it up for household and smelting use.

THE CUMMER ENGINE.

It is a gratifying evidence of the fact that economy is more closely studied in many branches of manufacturing and mining, that a better type of engines is beginning to find more general use. In the textile and other leading industries, progress in this direction has been rapid and well sustained for years; but it must be confessed that in our mines, and to a less extent in our rolling-mills and other metallurgical establishments, attention has been paid to the subject of economy of fuel only during the past decade. To a certain extent, this hesitation on the part of managers to adopt modern engines has been justified by the plea that it would not do to place a delicate mechanism where it could not get proper care, and that it was less uneconomical to waste fuel than to run up heavy bills for repairs and be subject to the annoyances and losses that frequent stoppages would entail. Experience has shown that many of the drawbacks have been overrated or have been met by more recent designs of engines, and the close margins under which works have been forced to run for long periods have taught the necessity of carefully studying economy in many departments hitherto neglected. To those in charge of such works is assigned the duty, and we believe most of them recognize it, of carefully watching progress; and there is therefore a more general disposition to look into the record and examine the claims of the growing number of engines of modern design which are now in the market. Among those engines which have, during the past few years, attracted considerable attention is the Cummer engine, first in the West, its home, and now in the East. We had occasion, some weeks since, to visit the well-appointed new shops of the Cummer Engine Company, at Cleveland, and to watch the methods adopted for building the engine, as well as to note its performance. A description of its principal features, and a presentation of the reasons for which details in the design and in the construction of parts were chosen, are its best advocates to attention. We need only add that we have been much impressed with the system adopted at the works to carry out the intentions of the designer.

The Cummer engine is an automatic cut-off engine, and therefore possesses the advantage common to the engines of this class of avoiding wire-drawing, using steam of higher pressure and admitting of closer regulation of the speed. As distinguished from the type of releasing automatic cut-off engines, of which the Corliss engine is the most prominent and successful example, the Cummer engine does away with the system of cams, springs, and tappets. The Cummer engine belongs to that class in which the valve, being at all times connected with the governor, has a positive motion. The cut-off is varied by shifting the eccentric around the shaft so as to change its angularity, and thus change the point of closure of the valve. This is effected through suitable mechanism by the movements of weights revolving in a vertical plane, their centrifugal force being kept in control by being made to lift a dead weight. Fig. 3 shows a vertical section through the center of the governor, and its parts—the plan, Fig. 2, also showing a horizontal section. The cut-off eccentric, with its sleeve, fits loosely on the governor-shaft, and, as shown in Fig. 4, is connected with the flying ends of the governor weights by means of rods or links in such a manner that the cut-off eccentric, with its sleeve, is moved around the governor-shaft, either forward or backward, as the flying weights change their position. Thus the steam is cut off correspondingly, earlier or later in the stroke, as the governor or flying weights adjust themselves to the load. As shown in Fig. 2, the horizontal plan of the engine, the governor-shaft is driven from the main shaft by a train of gears. It is hollow, as shown in Fig. 3, and through it passes a thrust-rod. One end of the latter is attached to a cross-bar which, passing through a slot in the governor-shaft, is made to revolve with it. This cross-bar is, as shown in Figs. 3 and 4, connected with the flying weights by bell-cranks and rods. The other end of the thrust-rod which passes through the hollow governor-shaft fits into a step which is jointed to the vertical arm of the large bell-crank shown in Fig. 3. Any movement of the weights in the governor case causes the thrust-rod to move correspondingly out or in, and thus raises or lowers the weight located under the engine, and through the rods and clamp-collar shifts the eccentric around the shaft in either direction, cutting off earlier or later as the case may be. The balancing of the centrifugal force of the flying weights of the governor by the constant centripetal force of the hanging weights would be perfect for the speed for which the governor is adjusted. An increase or decrease in the speed is taken care of by the spring shown in Fig. 3, the duty of which, however, is very light; this spring is adjustable by having its point of attachment shifted. The tension of the spring increases as the flying weights move outward, so that, when any change of speed occurs, the steam is cut off proportionately to the load, thus making the governor very sensitive within a wide range, without having the drawback of the changes which springs doing the whole of the duty undergo. By placing the governor on its own shaft, its diameter, and with it the size and friction of the eccentric and eccentric sleeves, may be reduced, and offset rods and offset rocker-arms be avoided. With small shafts, too, the points of attachment for the rods connecting the clamp-collar with eccentric sleeve with the governor weights may be brought much nearer the center of its shaft than would be possible if the eccentric sleeve was placed on the main shaft. For a given angular movement, the eccentric on a separate shaft need move through an arc only from one third to one fourth as large, and consequently a slight movement of the weights makes a much greater change in the point of cut-off and renders the governor more sensitive.

The main eccentric is, as shown in Figs. 2 and 4, attached to the end of the governor-shaft directly. It operates the main valves and then the exhaust-valves through the intervention of a rocker-arm. With the object of avoiding the derangement of the exhaust due to the use of the common D valve under same conditions, the Cummer Engine Company has adopted a separate steam and exhaust-valve, each with its own chest-ports and exhaust passage. They are operated from one eccentric and have each the same travel, while the cut-off valve slides upon the back of the main steam valve. In order to reduce the throw of the valves, and to use much smaller eccentrics, the "grid-iron" form of valve, shown in Figs. 5 and 6, has been adopted. Fig. 5 shows the main valve in plan and section; and Fig. 6, the cut-off; there being three openings in the former, while the latter admits steam from one of its outside edges and from corresponding inner edges of its two openings. The exhaust-valve

THE CUMMER AUTOMATIC CUT-OFF ENGINE.

has three openings, but, as one of its outside edges admits steam also, there are four ports in its valve-seat.

Fig. 7 shows an elevation, Fig. 8 a longitudinal section, and Fig. 9 a cross-section of the cylinder, in which appear the general features and arrangements of parts. The elevation shows in part-section the steam passage with a short length of pipe, and below it the exhaust passage. On each side, are the steam and exhaust-chests; that on the right has the cover removed, showing steam and exhaust-valves. The valve-stems are also shown; they pass through the steam and exhaust passages, and connect the valves at one end with those at the other. Fig. 9 is a cross-section through the cylinder and its base; the plane of section being through the valve-chest, shows the steam-valve with its cut-off, and

underneath them the exhaust-valve sliding in a horizontal plane. The exhaust-valve seat is made removable, for greater convenience of construction and to allow for refacing. Below the exhaust-valve is seen the exhaust passage, and there is also shown the means by which the valve is moved; this consists of a clamp-collar which fits the valve-stem and is provided with a prong coming up through a slot in the valve-seat and attached to the valve. One half of the horizontal section, Fig. 8, shows the main and cut-off valves for that end with its steam passage. The other half is sectioned to show the exhaust valve-seat. In this figure and also in the cross-section, Fig. 9, we see how the steam enters the cylinder through a three-ported seat, afterward uniting to form but one opening into the cylinder, and how steam is exhausted through the lower part of this same port, which then by one large opening communicates with the chest in which the exhaust-valve is located. There is no real connection between the two, however; each valve within its own chest controls its own ports, and live steam can not enter the exhaust. In Fig. 8, there is a sectional view of one cylinder-head; this is inclosed by a conical shaped cover fitting air-tight; its surface is polished so as to look well and prevent radiation, while the air in the interior space acts as a non-conductor of heat. The head for the opposite end is formed by the inner end of the frame, which fits into the cylinder and is bolted to its flange. The cylinder itself is covered with non-conducting material, and the whole inclosed by a neat cast-iron lagging.

The piston is made large enough to give ample wearing surface, and with sufficient weight and careful distribution of metal to secure strength, no extra weight being given for any other purpose. The piston consists of three parts: the piston proper, to which is fitted the tapered end of the piston-rod secured by a cotter; the chunk-ring; and the follower. These parts are all clearly shown in the section. The plan exhibits the piston with its follower removed, but showing in section the four bolts which hold it in place when connected. It will be noticed that the piston itself and also the follower are made considerably smaller than the cylinder, and that the chunk-ring is external to these, and forms the bearing surface. The chunk-ring is turned up so as to be an accurate fit, and is then adjusted so as to be perfectly central by means of four stud-bolts, which appear in the plan and section; their outer ends have a conical point which bears against the chunk-ring, while the other ends are tapped into the boss of the piston and are provided with jam-nuts. The center of the chunk-ring is grooved, to receive the cast-iron piston-ring, which is pressed outward by several small spiral springs spaced around the circumference. The positions of these springs appear in the plan, and one of them is shown in the section. An additional packing is provided by turning two small grooves in the chunk-ring on each side of the central piston-ring. The advantage of using a chunk-ring is, that a very exact fit can be made, and, by using the central adjustment, perfect alignment can be secured. A greater wearing surface for the same thickness of piston is obtained, because the chunk-ring is the same width as the piston itself and bears over its whole surface, whereas, in the ordinary form, a part of the piston, and the follower also, are turned down below size and do not bear at all. By this arrangement also, whenever, after long wear, it becomes necessary to rebore the cylinder, it is only necessary to turn up a new chunk-ring instead of fitting up a whole new piston.

In the vertical section, Fig. 2, is shown the form of cylinder-head adopted by the Cummer Engine Company. It projects within the cylinder, and is designed to reduce clearance to as low an amount as possible. The forward head, as shown in the engraving, is formed by the end of the girder frame, but, in the company's present practice, the head is made separate and bolted to the frame. Objections have been made against this deep form of cylinder-head, on the ground that the annular space between the head and counter-bore affords so much more condensing surface than the ordinary form of cylinder-head; but, in point of fact, this objection does not hold at all, because the cylinder-heads are made a true fit for an inch or so at the outside bearing and an easy sliding fit for the rest of the length. The space between the counter-bore and head, which is about the thickness of a piece of paper, becomes, when in use, completely filled up with a deposit from the oil used to lubricate the cylinder, which is driven in by the steam, and, as experience has shown, effectually prevents any condensation from this cause.

DRIVING MACHINERY BY SAND.—A Western exchange gives an interesting account of the method recently adopted by Mr. J. Townsend, of Virginia City, to run a number of arrastras by sand. The arrastras are placed in a light sandy field where only sufficient water for drinking purposes and to moisten the ore to be operated upon can be obtained. The sand drives a large overshot wheel, taking the place of water. It was at first Mr. Townsend's intention to run the arrastras by means of a large windmill; but as the speed was naturally irregular, he adopted the present method. The windmill now runs a belt containing a number of buckets, and these carry sand up to a large tank somewhat in the way that grain elevators carry wheat. A stream of sand being let out upon the overshot wheel, causes it to revolve, just as it would under the weight of a stream of water, and thus far the method is said to have been found very successful. When there is a considerable wind, sand is stored up for use when calms prevail, and in this manner the mill may run continuously.

THE MINING AND METALLURGY OF ZINC IN THE UNITED STATES.*

By F. L. Clero.

(*Continued from page* 151.)

EASTERN ZINC-WORKS.

Spelter Furnaces.—The reduction-works at Newark, Jersey City, Bergen Point, and Bethlehem employ the same general type of furnace, adapted to the use of anthracite coal. They all manufacture oxide of zinc as well as spelter. None of them can produce metal as cheaply as any of the Western works; but they all produce a brand of metal very free from lead, which commands a continued sale. The furnace used differs from the ordinary Belgian furnace chiefly in the substitution of a shallow ash-pit from 16 to 18 inches deep, with luted ash-doors, into which a blast of air is admitted under the fire, in place of the high underground ash-pits and tunnels of the latter. The grate is composed of flat perforated bars of cast-iron, placed close together, so as to permit the use of pea coal. The method of cleaning the fire is as follows: At the back end of the grate, and on a level with it, there is a flat ledge of fire-brick; the live coals from the top of the fire are pushed back on to this ledge, the cinders are barred up from the grate and scraped out at the fire-door; the fire is then drawn forward and spread over the cleaned bars, fresh coal is thrown in, and the blast is admitted, and in a very short time the furnace is brought to the required heat. By means of the blast and chimney-dampers, the fire is easily controlled, and the heat is regulated to suit the requirements of the different operations of smelting. Furnaces of fifty-six retorts are in general use. Nothing seems to be gained by any considerable increase in the number. If the furnace is charged twice in twenty-four hours, which is the usual practice, this is about as many as can be attended to properly by three men—one charger and one long-shift and one short-shift man; for if the operation of cleaning and charging is prolonged, the time left for reduction becomes too short to properly exhaust the charge. If the furnace is enlarged so as to employ two more men, the work of firing becomes excessive if there is only one fireplace; if there is a fireplace at each end, a cross-wall between them adds little to the cost of construction, but it greatly strengthens the block and facilitates repairs; but at the same time it divides the block into four furnaces. Anthracite coal, with a blast, gives a good flame and sufficient heat in all parts of the furnace. It is customary to protect the lower retorts from the radiated heat of the fire by a row of thick tubes, called cannons, about the same size as the retorts, but open at both ends. Where the furnace is charged only once in twenty-four hours, much time is lost, during which part of the furnace is not working; and the lower retorts are too long exposed to a strong heat under circumstances which make it very destructive to them. It may also be considered as proved that any considerable departure from the long-established dimensions of the retorts—from 6½ to 7 inches internal diameter—is a mistake where the furnace is charged twice in twenty-four hours and the ore is sufficiently valuable to make close working desirable. It is worthy of note that the workmen everywhere desire larger retorts and twenty-four-hour charges, for the simple reason that their active working hours are reduced at the same time that the amount of metal on which they are paid premium is increased.

Oxide Furnaces.—The oxide furnaces in use are also of the same general type. Each furnace has a rectangular horizontal cross-section, about 3½ feet wide by 6 feet deep, and is covered by a full center arch; 8 or 10 inches below the spring line of the arch is the grate, which is formed of flat cast-iron bars, 6 feet long, 6 inches broad, and an inch thick, perforated by tapering holes, one inch diameter below and one quarter inch diameter at the top, set as closely together as the strength and stiffness of the iron will permit; these bars lie close together, and rest on three or four bearers set crosswise into the side-walls of the furnace. Below the grate is an ash-pit from 18 to 20 inches deep, closed in front by iron doors. The opening into the furnace is under an arch in the front wall; this doorway is sometimes closed by iron doors, but the simplest and best method of closing it is with a bank of moistened ashes piled up against it; for this purpose, a shelf about 20 inches broad projects in front of the furnace on a level with the grate-bars. The front opening is usually a semicircular arch the full width of the furnace. The ash-pit is connected with an air-flue coming from centrifugal fans, and provided with a damper, by which the blast is regulated. There is an opening in the arch of the furnace for the escape of the zinc oxide and other products of combustion; this opening either leads directly into the iron or brick flue running to the cooling apparatus, or into a short flue, from which the gases may be turned either into the oxide flue or into an open chimney, according to which of the two systems of working is adopted. It is customary to place two such furnaces end to end, and work them from opposite sides; and the end wall between them is sometimes omitted, a single opening through the arch answering for both furnaces. A row of such pairs of furnaces side by side is built, and the same air and oxide flue answers for the row.

The method of working the furnaces is as follows: One man attends to four or six adjoining furnaces, and charges them alternately, one every hour. When opposite furnaces open into each other, these two furnaces are charged at the same time. When the time comes for cleaning out a furnace, the draught is shut off, the pile of ashes is removed from the front of the furnace and thrown to one side, to be used again. What is left in the furnace from the preceding charge is in the form of a more or less solid clinker, covering the whole surface of the grate: this is loosened and broken up with suitable bars, and is drawn out in front of the furnace. The bed coal is thrown in on the cleaned grate, and spread evenly in a layer of about an inch deep, the front opening is partly closed with a loose piece of sheet-iron, and a little air is admitted through the ash-pit; the cinders and ashes of the preceding charge are thrown out of the way of the workman, and, by the time this is done, the bed coal has been sufficiently ignited from the heat retained in the sides and arch of the furnace to receive the charge. This consists of a mixture of crushed ore, with about half its weight of anthracite coal, as finely crushed as can be used without falling through the grate. The charge is spread over the fire and leveled carefully; the front of the furnace is closed with its bank of ashes, and more blast is let on. A charge remains in the furnace from four to six hours, according to the practice at different works. When the ore used is calamine, smithsonite, or franklinite, it is charged raw; when it is blende, it must be very carefully roasted beforehand. When franklinite is used, the hard clinkers remaining in the furnace are reserved for the manufacture of spiegeleisen, and are called the "residuum." The fine residues of the charge are mixed in with the succeeding charge; by this means, the fire is kept open for a longer time for the penetration of the blast, and a thick crust of residuum is obtained, more suitable for treatment in a blast-furnace. The ashes are removed from below the grate only once in twenty-four hours, and the charge is in all cases slightly moistened before being thrown into the furnace. As the charges are made alternately every hour, the heat in the conduits and all parts of the apparatus is kept very uniform, and sufficient to instantly burn any particles of coal drawn over with the gases, and no trouble is experienced from their effect on the oxide. The practice of some works in only turning the gases into the oxide flue when the zinc flame makes its appearance, seems an unnecessary precaution. An excess of air is always admitted, so that it is probably the active agent in oxidizing the zinc, and very little carbonic oxide would be found in the bag-room. It is very important that the men should watch the working of the furnace carefully, and by regulating the admission of the air, and by closing all blow-holes with a rake, should force the air to pass through the charge as uniformly as possible.

The apparatus for cooling the gases and oxide varies considerably in different works, but consists essentially in some combination of brick or iron flues, with towers or ascending pipes, with or without sheets or jets of water and steam-chambers. Beyond it are exhaust-fans, to draw the gases carrying the oxide from the furnace and send them through settling-chambers to the bag-rooms. The gases, now cooled and carrying only light flakes of merchantable oxide, are distributed through the bag-rooms by iron branch pipes, along the tops or the bottoms of which are set rows of nipples close together, to which are attached cotton bags. These bags are often 40 or 50 feet long, and hang down from the branch pipes or are suspended vertically above them from the roof. Two hundred square feet of bag surface to one square foot of grate surface is a proportion found to work very well in practice. The bags are about two feet in diameter, and, when suspended from the branch pipes, the lower ends need not be closed if they are long enough to be given a half-twist and rest on the floor or on a slightly raised bench under them. An ingenious variation of this arrangement may be seen in the works of the Lone Elm Company, at Joplin, Missouri, for the collection of the white fumes from the lead slag eyes. There the lower ends of the bags are tied to nipples in the top of closed bins, into which the collected fume may be directly shaken, and from which it may be packed, when the lower ends of the bags are closed by a sliding gate. The bags thus form the only outlet from the furnaces. The cooled gases pass freely through the meshes of the cotton, and the finest flakes of oxide are arrested on the inside. These must be shaken down from time to time, to keep the meshes open and to collect the oxide in the bottom of the bags. When the oxide, after collection, is kiln-dried to drive off one or two per cent of moisture absorbed from the furnace gases, and bolted to remove cotton fibers and occasional specks of iron-rust and lumps of hardened oxide detached from the pipes, its quality is certainly improved, and it will keep better without caking; but this is not always considered necessary. As collected, the oxide is too light and feathery to be directly packed, and must be compressed by suitable machinery.

This oxide process is not new, and is generally well known, but it is probably the only valuable contribution America has made to the metallurgy of zinc. Its operations, though very simple, are not without their difficulties. Very slight and often not very obvious causes suddenly affect the color or body of the oxide; different ores require different treatment, and the heat conditions and amount of air admitted at different points of the apparatus seem to have almost as decided an effect on the quality of the oxide as has the character of the ore treated: all of the volatile constituents of the ore will be found in the oxide. Besides containing traces of sulphur, arsenic, antimony, and cadmium, commercial oxide frequently contains minute but weighable amounts of lead, iron, manganese, lime, magnesia, and ash, which often do not seriously affect its color. If the color is good, a small percentage of lead is supposed to add to the body of an oxide. There is good reason to infer that the unnatural color imparted to an oxide by these elements depends much less on the actual amount of them which it contains than upon the nature of the compounds into which they enter, some of these compounds being white, others possessing more or less coloring properties. Conditions of volatilization, oxidation, and condensation, therefore, strongly determine the color of the resulting oxide. Color being a purely physical property, it is also probable that, apart from the effect of extraneous coloring substances, the color of an oxide depends also on its physical texture, and sometimes results solely from physical causes. There must be a certain proportion between the volume of gas, the amount of oxide carried by, and the dimensions of the flues. Apparatus that will work very well with certain ores, or with a certain number of feet of grate surface, will not give equally good results with richer or poorer ores, or with more or less grate surface. In working some ores, it is necessary to run as hot as is consistent with safety to the different portions of the apparatus; with others, the best results are obtained by running cold. It is well to start with sufficient cross-section of flues, and with a reserve of power in blast and exhaust-fans, and with large cooling and settling-chambers, and numerous doors for cleaning them and admitting air. Water in the ash-pits is in some cases found to be very useful in protecting the grate-bars and equalizing the temperature. Considerable control can always be had over the heat by varying the weight either of coal or ore in the charge; both must also be regulated to suit the time the charge is to remain in the furnace. Lime or limestone is often added to the charge, and acts sometimes chemically in liberating the zinc from its combination with silica; at other times, it is added to stiffen the charge and prevent it from running through or stopping up the grate-bars.

In the works at Jersey City, Newark, and Bethlehem, franklinite is now exclusively used for the manufacture of oxide, and the residuums are treated for the extraction of the iron and manganese in small cupola

* From advance-sheets of *The Mineral Resources of the United States*, published by the United States Geological Survey, Department of Industrial Statistics. Albert Williams, Jr., Chief of Department.

Digitized by Google

furnaces, about 20 feet high above the tuyeres, and 6 feet wide above the boshes. Nearly all of the iron is obtained, but little more than half of the manganese. The operation is beset with many difficulties. The 3 or 4 per cent of zinc oxide left in the residuum is very troublesome, and has heretofore prevented the use of large furnaces. The pipes for collecting the fumes from the tunnel-head require cleaning two or three times a week, and during the cleaning the furnace cools down and manganese goes into the slag; the spiegeleisen drops suddenly from as high as 23 per cent often below 10 per cent of manganese, and eight or ten hours are required to bring the furnace back again to its proper working condition. If the manganese could be got into the pig to the same extent as the iron is utilized, a ferro-manganese of 33 per cent could be obtained.

The fumes collected from the spiegel furnaces and the impure oxide obtained from the flues and sweepings of the oxide-works are usually made into metal in the ordinary spelter furnaces, but the latter is sometimes converted into good oxide by reburning.

(TO BE CONTINUED.)

MISTAKES IN MINING.

Written for the Engineering and Mining Journal by George C. Tilden, C.E.

While spending the summer vacation in Clear Creek County, Colorado, the writer noticed that it was unusually quiet, and although the usual quantity and quality of mineral were sold to the sampling-works at an unusually high rate, there was a lack of activity as far as concerned investments. There were but few new mines worked, and some of the old ones, which have been and are still capable of producing large quantities of ore and at fair profit, if properly managed, were idle. As a cause of this, it was suggested that Clear Creek County had lost favor with Eastern capitalists, because it had not done what they expected it would. If the mines of this county can not influence capital, it is not caused by any want of value on the part of the mines, but through mistakes made by the capitalists themselves. To call attention to a few of these mistakes, without reference to the mines at which they were made, will not be out of place.

It is a mistake to believe that a vein is a continuous ore-body that will always carry ore, and that the assay value of the ore will increase as depth is attained. It is a mistake to believe this, and provide no capital for development. It is a mistake to expect from a mine, when once opened up, more than a fair percentage of profit on a fair valuation. It is a mistake to judge of the value of a mine, or even of a stope, from specimen assays. It is a mistake to accept the opinion of a young mining engineer, fresh from some Eastern mining college, in regard to a mining or milling investment. The young man in taking charge of the property obtains considerable valuable information and experience; but his company unfortunately has to pay for it.

The above is written with no intention to disparage graduates of institutions of technical training, but to imply that theory in mining is useful only in so far as the mining engineer is capable of combining it with practice. We have had altogether too much of the theoretical man in Colorado. He has made the greatest number of mistakes. He comes here intrusted with business important both to the reputation of our State and to the interest he represents. All theory—no practice—no business education. He thinks mine management a profession. It is a business as well. Ground is to be let. This requires a knowledge of its value per foot or fathom for breaking, and the royalty it can command. Contracts are to be made. Rents are to be determined, and other business to be transacted. Mineralogical, geological, or any technical training, although of great value, is not all that is required. The manager of a mining property must have a business knowledge of mining. Surely the man of theory has left his mark in Clear Creek County.

It is a mistake to sink a perpendicular shaft and drive a cross-cut to work the veins of Clear Creek County, when in every case an incline would be less expensive and answer the purpose as well. It is a mistake to drive a cross-cut tunnel fifteen hundred feet, at an expense of at least twenty-five dollars per foot, and not secure a title to a single vein that it will intersect. It is a mistake to work the mines of Clear Creek County by any other than the "tribute system." It is a mistake to build tramways, concentrating or stamp-mills when there is only a prospect of obtaining ore. It is a mistake to build a plant to treat ore by some new "ten dollar a ton and save ninty-nine per cent of the assay value" process, without first making a thorough but comparatively inexpensive inquiry into the chemical and mechanical laws upon which the new idea is based. It is a mistake to run a mine in debt and then expect to pay up by allowing the tributers to produce the greatest quantity of mineral in the shortest space of time by gouging and understoping. It is a mistake not to keep the development-work of a mine in advance of the work of extraction. In Clear Creek County, it is a mistake not to open up at least five fathoms of ground for every fathom stoped. It is a mistake to build a forty thousand dollar mill on property that belongs to some outside party who, after completion, will give a lease for only a year. It is a mistake to think that the merchantable ore of Clear Creek County will pay the cost of transportation to a concentrator that is far remote from the mines. I fear it would be a mistake to attempt to treat the ores of Silver Plume at that place, as has been suggested by some. They do not contain enough lead for treatment in a water-jacket. They contain too much lead to waste by any process that does not secure the lead. They contain too much zinc. They are too refractory. The only advantage they possess is their grade. They command the very highest rate in Golden and Denver, when they are mixed with less refractory ores, and only by judicious mixing can they be smelted with profit. Mining in Clear Creek County is profitable, but not to parties who make the mistakes I have mentioned. No enterprise can succeed where errors of equal importance occur.

THE DUTY ON ROUND IRON.—The Customs Division of the Treasury Department is in daily receipt of letters complaining of the decisions of collectors of customs with respect to the tax on round iron and wire rods. Nothing, however, will be done toward settling the dispute as to the construction of the tariff act in so far as it relates to this class of imports until after Secretary Folger returns to the department. With the object of securing the fullest information possible on the subject, Assistant-Secretary French, about two weeks ago, addressed a letter to the secretary of the Iron and Steel Association in Pennsylvania, asking for data and for his views regarding the construction of the law; but up to the present time, the desired information has not been received from the association.

TUBES AND WIRES UNDERGROUND.—The pipes for the pneumatic tube service of the Western Union Telegraph Company are laying between the building of the company at Broadway and Dey street, and the new building at Fifth avenue and Twenty-third street. Four brass tubes, each 3 inches in diameter, will be put down. In the same trench will be laid two 5-inch iron pipes for holding telegraph wires to be used in local business. The company now has 75 miles of wire underground between the main building and the Stock and Cotton Exchanges and the North River cables. The pipes are laid four feet underground, to be out of the reach of the frost. The pneumatic tubes will be in operation early in the winter. Pneumatic tubes now run to the newspaper offices, the Stock and Cotton Exchanges, the Equitable Building, and the cable offices. The new Produce Building will be connected with the main office in the same way.

THE PRODUCTION OF AUSTRIAN MINES AND SMELTING-WORKS IN 1882.—Official statistics have just been published on the production of the mines and works of Austria in 1882. The unit is, unless otherwise stated, the metric ton of 1000 kilograms:

Mines.	1882.	1880.
Coal	6,559,002	5,889,631
Lignite	8,996,290	8,420,647
Iron ore	902,510	696,832
Graphite ore	15,577	13,718
Manganese ore	8,418	8,874
Smelting-Works.		
Pig-iron	435,478	320,302
Spelter	4,791	3,756
Copper	482	500
Lead and litharge	11,889	9,235
Quicksilver	409	369
Tin	34	29
Gold (kilograms)	16·4	41·3
Silver (")	31,095	30,257
Antimony	161	125
Sulphuric acid	12,282	12,234

FURNACE, MILL, AND FACTORY.

Says the *Philadelphia Record:* Nine vessels loaded with Bessemer ores from Spain, each carrying from 1800 to 2000 tons, are expected to arrive at this port within the next two weeks. An old iron broker of this city, in commenting upon the fact yesterday, stated that this was an unusual occurrence. Three years ago, it would not have been considered so unusual, as the arrival of that number of ore-laden vessels in this city was a frequent occurrence. Philadelphia in those days ranked first in prominence as a port of entry for vessels with cargoes of that kind. This prominence, he contended, had been transferred to Baltimore. The reasons given for the diversion of this traffic from one city to another were numerous.

The gas-well at the Laughlin nail mill, Harper's Ferry, is going down as fast as possible.

The Benwood Iron-Works, Wheeling, have begun the work of boring for gas on their property between the mill and the Baltimore & Ohio Railroad.

An innovation in the manufacture of iron in Cleveland has been the recent introduction of Canadian ores. These hematites have been introduced into the burden of the Central Furnace of the Cleveland Rolling-Mill Company in the proportion of 25 per cent to 75 per cent of Lake Superior ores, and with very satisfactory results. The Hocking Valley coal and iron syndicate has also, we learn, arranged to give these ores a trial.

The Crozier iron furnace at Roanoke, Va., turns out one hundred tons of first-class metal per day. They use coke from Pocahontas. The ore is supplied from the Houston mines, fifteen miles distant on the Shenandoah Valley Railroad, and from the Upland mines, twelve miles distant on the Norfolk & Western Railroad.

Smethport, Pa., is to be lighted and heated with natural gas by November 1st, from the Wilcox gas-well, sixteen miles distant.

The blast-furnaces of the Joliet, Ill., Steel Company are running steadily. The converting mill and rail-mill are making 175 tons of rails at a turn, or 350 tons every twenty-four hours.

From Pittsburg, it is reported that it is proposed to start up the sixteen puddling-furnaces built a year ago at D. J. Painter & Son's mill. The puddlers at Everson & Macrum's mill are to go on double-turn. Work on Moorhead & Co.'s new open-hearth steel-furnace is pushed ahead.

The Farrell Foundry and Machine Company, at Ansonia, Conn., has added a 60 horse-power Westinghouse automatic engine to drive all its foundry work, independently of its main engine and water-wheel. It is also using a smaller one as an independent power for the blower in the forge.

The Western Nail Association held its regular quarterly meeting at Pittsburg, September 12th. Reports received from all sections indicate the trade to be satisfactory, and that plenty of orders are coming in. Stocks are reported to be very light and assortments badly broken. In view of this, it was decided not to order a stoppage of the mills, as was anticipated, but to continue them in operation until further orders. The card rate was not changed.

Reports from Niles, Ohio, state that ten of the business men of that place have incorporated the Goshen Iron Company, with the view of purchasing the interest of the Ward Iron Company in the New Philadelphia rolling-mill. The new company designs paying off the liens on the mill as soon as possible, and will avail itself of the benefits accruing from the town according to the original contract. The capital stock is $300,000.

At Chicago, on the 12th inst., the Washburn & Moen Manufacturing Company, the patentees of barbed wire, filed a bill in court to restrain the Lyman Manufacturing Company from manufacturing more than 2500 tons of barbed wire annually, according to contract. The damages for over-manufacture are laid at $100,000.

At Clinton, Mass., the Clinton Wire Cloth Company is putting in apparatus for galvanizing the wire cloth at its mills. Hitherto, this part of the work has been sent elsewhere to be done.

A conference has been arranged for the 15th, between the proprietors of the South Chicago Rolling-Mills and a committee of the striking employés. It is understood that the men are ready to resume work on the company's terms, and the general impression is, that work will be begun in two weeks.

The Mont Alto Charcoal Furnace, 9½ by 43 feet, resumed work a short time since after an idleness of three months. Fire was lighted in the furnace on Tuesday morning, August 14th, and the output during the first twenty-four hours was 5¼ tons No. 2 and 8⅓ tons No. 1, a total of 14 tons of pig-iron. During the

Digitized by Google

second twenty-four hours, the product was 30 tons No. 1 pig on less than 100 bushels of charcoal per ton of 2268 pounds of pig-iron. Since this remarkable start, the furnace has continued to do excellent work.

The Florence, Mich., *News* states that there is some talk among the Florence mine management of building a blast-furnace at the mine at no distant day.

The Fort Scott Machine Works, Fort Scott, Kansas, have received an order for a concentrator for the works of the late Alta-Montana mine.

GENERAL MINING NEWS.

ARIZONA.

GRAHAM COUNTY.

ARIZONA COPPER COMPANY.—The furnaces have been closed down, and the work of clearing away and getting ready for the new plant of five furnaces and concentration-works has already begun. The Clifton *Clarion* says that the new plant will be built about ten feet higher than the present furnaces, on the side of the hill, which will give a good fall for the slag. The narrow-gauge railroad will be raised so as to come in about 70 feet higher up on the hillside than the furnaces, and a side-track about 40 feet below it. Large chutes will be erected to receive the ore as it is brought down from the mines, and bins and sheds will be built to contain the coke. The high-grade ore will pass from the chutes into the crushers and from there to the furnaces, and the ore of a low grade will pass into the concentration-works and then to the furnaces. A new water-power is also to be constructed. The water will be taken from the San Francisco River, and a flume 4000 feet in length, four feet deep, and seven and a half feet wide, will be built, which will furnish ample power for the new plant and also for any additional works that may be required in the future. Every advantage will be taken in constructing the new works to facilitate economical operation.

PIMA COUNTY.

A correspondent of the San Francisco *Exchange* says: The project of putting up reduction-works in Tucson is by no means dead. Every day shows more the need of them, and shows also that they will not only be a financial success themselves but a great advantage to the surrounding mining districts. There are many rich ledges in this vicinity which would not warrant reduction-works, but which could ship ore to Tucson and reap a large profit.

OMEGA.—This smelter will start up shortly.

PEER.—This mine is situated in the Quijotoa Mountains about eighty miles southwest of Tucson. The ledge is from 15 to 20 feet wide, and may be distinctly followed for 3000 feet, cutting through a high butte, where it displays itself clear to the bottom of the gulch. Five tons of the ore have been sent to Benson, and the owners received between $400 and $500 per ton. But little work has yet been done on the claims. The work going on now is sinking for water, the nearest water now being four miles from the mine.

PINAL COUNTY.

SILVER KING.—The damages made by the recent storms have been repaired and work continues as usual.

CALIFORNIA.

INYO COUNTY.

LASKY MILL.—Of late, this mill, at Beveridge, has not been running very steadily, and has been crushing only fifteen hours out of the twenty-four. Since the 22d of July, it has reduced 80 tons of Keynot ore which resulted in 340 ounces of gold at $14, amounting to $4760. Twenty-one tons of ore from the True Business mine were also crushed, which yielded 75 ounces of gold, worth $15 per ounce, amounting to $1125. The works are now in steady operation, and there is plenty of ore on hand.

COLORADO.

ARAPAHOE COUNTY.

EUREKA SMELTING AND REFINING COMPANY.—A small plant of machinery has been put up by this company in South Denver, where it is working ore by the new Brett process. It is claimed that by this process ore can be treated at from 90 cents to $1.15 a ton, or for $1.50 at the very highest. Three men are employed at the new works, which has a capacity of about fifty tons a day. It is understood that ground is looked for on which to erect capacious works, and that a party of capitalists is backing up the enterprise.

PUBLIC SAMPLING-WORKS.—This company, which has a plant at Black Hawk, has begun operations by erecting similar works in Denver. The works, it is estimated, will cost $25,000.

CHAFFEE COUNTY.

HORTENSE.—This mine has been leased. It is one of the best developed properties in the county, containing over two thousand feet of tunnel and drift. There is also a wagon-road to the mine, which cost $6000. A great deal of money has been expended on the property, and a considerable amount of good ore has been shipped. Only a small force has so far been put to work, but more men will be employed in a short time.

TWIN LAKE HYDRAULIC COMPANY.—A large amount of work will be shortly commenced by this company near Vicksburg. It will take out a ditch from Clear Creek, to work its placers in Cache Creek, which will involve the construction of about seven or eight miles of ditch and flume and a tunnel 1800 feet long through the divide between the creeks. It will be recollected that the company recently purchased the rich placers in Cache Creek, lately owned by the Gaff Mining Company. The chief difficulty heretofore experienced, a lack of water, will be entirely obviated by this new enterprise.

CLEAR CREEK COUNTY.

Under date of September 7th, Mr. Linwood O. Towne sends us the following notes from Rico:

GRAND VIEW.—Something of the nature of a "strike" has been taking place for the week past among a large number of the workmen employed by the company. Work at the smelter has, however, not been interrupted, new men being found without difficulty where necessary. Besides Rico mines, the Silver Bell of Ophir is furnishing a large and constant supply of ore to this smelter.

LITTLE MAGGIE.—This mine is now working a force of men, and shipping ore daily to the Grand View smelter. Development is being pushed by means of a tunnel now in 320 feet, and in incline, down 100 feet, with drifts from the latter. The shipments, which are mainly from the tunnel, consist of carbonate and sulphate of lead, running well in silver.

NEWMAN GROUP.—It is rumored that this group, on which, for some unknown reason, no work has been done all summer, will soon be opened and worked under the efficient management of Mr. F. W. Reed.

SOUTH PARK.—The main tunnel is now in 400 feet. Within a few days, a small quantity of low-grade lead carbonate was exposed, which, however, at once changed into the usual high-grade sulphide and native silver, which latter has been found in greater abundance in South Park than elsewhere in Rico.

MATTIE.—During August, seventy-one tons of smelting ore were shipped, which netted the company $7300. At present, the third level shows a continuous ore-body, which in the breast is about a foot wide solid, besides mineralized quartz aarying in width from six to twenty inches. The ore is mainly gray copper, and at this point seems even richer than that hitherto traversed. This month the output will be largely increased over August.

HINSDALE COUNTY.

CROOKE MINING AND SMELTING COMPANY.—The output of the Ute and Ulé for August was 600 tons. The new shaft from the third level of the Ute is 60 feet deep on a 4-foot vein. The quartz is banded with 10-inch streaks of mineral. Should the width of vein continue in the level below as above, it will open stoping ground for two years at an output of 300 tons a month. The Ulé drift west in the 7th level continues its usual production of ore. This level has been drifted 250 feet over a fine body of ore. The stopes above are producing largely. Up to September 1st, there were 2400 tons of concentrates stored in Lake City by this company.

LAKE COUNTY.

AMIE.—The No. 2 shaft has been leased, and parties are now making preparations to work the mine. The belief is current that quite a body of mineral still remains in the stopes to the south of the shaft, now inaccessible on account of the caving of some of the drifts. To reach the prospective bonanza, the present lessees will drive a drift on the 130-foot level to the southwest, and penetrate the old stopes.

BIG CHIEF.—The drift driven to the east and starting from a point near the Castle View shaft, is about 150 feet in length, and at its face a winze down 25 feet shows five feet of ore and 20 feet of good iron. The ore runs from 50 to 60 per cent in lead and from six to ten ounces in silver, and is a fine gray sand. The iron also runs well in silver.

CATALPA.—The lessees have done considerable exploration-work within the past few weeks, resulting in the development of several small ore-bodies. The mine has begun extracting ore and will resume shipments shortly.

CHRYSOLITE.—The iron incline from the Colorado shaft No. 2 is now within about 275 feet of the Roberts shaft. Recently the mineral showed a great improvement, but before development could be sufficiently advanced to prove up the prospective mineral body, the water drove the miners out. During the past few days, three pumps have been kept in active operation in the incline, and the water is lowering quite rapidly. The draining of the incline is also affecting the Roberts shaft, in which the water is falling at the rate of about two feet per day. The ore-shipments from the mine are about the same as for a number of months past. The company has about $240,000; one half of which is loaned out drawing four and six per cent, and the remainder is out on call loans. The revenue derived from its capital is ample to pay the expenses of the company in the East and leave a surplus. Although a great deal of expensive exploration has been done in the past twelve months, the earnings of the mine have been in excess of the expenditures, and the fiscal year will show a slight gain.

COLONEL SELLERS.—The lessees of the lower shaft are reported to have struck ore at a depth of 210 feet. The mineral is iron pyrites and galena. The Little Helen shaft, adjoining, is also reported in mineral.

DOLPHIN.—In this property, adjoining the Matchless mine on the south and west, new developments have been made recently, which promise to permit the mine to make extensive shipments of rich ore again. For some time past, the mine showed little or no pay ore, and considerable exploration-work was done, which finally resulted in opening a body of black iron ore, situated west of the working-shaft. The mineral carries no lead, but considerable chloride of silver.

HIBERNIA CONSOLIDATION.—The recent strike in the new south shaft on the May Queen claim proves to be one of the most important and remarkable discoveries made this year. For years past, exploration-work has been in progress on this hill, and innumerable new shafts have been sunk, without success, however, until the present shaft was put down. Sinking has progressed, and the development now shows twenty-one feet of ore, and the dump contains at least eighty tons of fine shipping mineral. The new strike gives promise of opening out a large shoot of ore, the trend of which is carrying it through the heart of the Hibernia Consolidation and other properties to the east.

IRON SILVER.—Several hundred tons of ore have already been taken from the recent strike in the Moyer shaft.

LEADVILLE GOLD AND SILVER MILLING COMPANY.—The mill, idle for some weeks past, will resume operations the early part of next week. The mill is now receiving ores from the Robert E. Lee dump, and, when started up again, will run regularly.

LITTLE CHIEF.—A settlement was made by this company with the smelter for the first ore from the new strike, and amounted to fifty-eight tons net weight. The ore averages 154 ounces to the ton. The mine also settled for a small lot of ore sorted from the old dump, which returned about $1000. The two settlements returned the company, $10,000, will be transmitted to the New York office. There are four additional lots of ore at the smelter, which will be settled for in a few days. Two of these are mineral extracted from the new ore-body, while the other two are second and third-class material. It is calculated that the mine will earn during September at least $20,000, and possibly considerably in excess of this amount. The new ore-body is not as solid at present as it was a week ago, the high-grade ore being scattered through the iron. One breast, however, shows about ten feet of $50-ore, while in portions several feet of $100 to $150-ore are exposed. The drifts running on mineral are advanced. The first, having a northwesterly course, has a length of forty-five feet, the other heads to the northeast, and is in ten feet. Both drifts show good ore.

The favorable result of the new strike shows itself in a dividend of $20,000, payable October 9th. This dividend is the first declared since August, 1880.

MAID OF ERIN.—That portion of this claim not in conflict has been leased to parties working the Big Chief mine. Considerable high-grade ore is taken out.

NEW PITTSBURG.—The Keene shaft, which had a depth of 217 feet when work was begun, is down 328 feet. A drift is driving from the bottom of the shaft to the southwest. An incline is also worked, having an easterly course. The product of the mine is not as large as it was some months ago. For some time past, the Heytrosser shaft has been worked for iron. The mineral carried from ten to twenty ounces in silver to the ton, and forty per cent of iron in excess of the silicon.

PILOT.—This mine, on Printer Boy Hill, recently shipped three loads of ore to the Elgin Smelting-Works, averaging about thirty dollars per ton above smelting charges. The mine is now reported to show about five feet of ore, from which assays have been obtained of seven ounces in gold and fourteen in silver to the ton.

PARK COUNTY.

The Hall Valley camp is fast coming into prominence, and bids fair to soon rank with the best ore-producing districts of the State. A correspondent of the Denver *Tribune* says that the extensive and very complete mill fitted up during the past year by the Quincy Mining and Milling Company has afforded an opportunity for treating the ores, which until now have lain on the dumps awaiting the time when the means for their treatment should be furnished. As a direct result, more claims have been worked this season than ever before. The Hall's Gulch Consolidated Mining and Tunnel Company has been working the past two years, and is now rewarded by a splendid showing of high-grade ore, particularly in the shaft now sinking on the Great Eastern. At a depth of 100 feet, a vein about two inches wide has appeared, showing black copper and silver glance. The ore-bodies in the several shafts and tunnels show veins of bismuth and copper ore, carrying silver from 18 inches to over three feet in width, and mill-runs on car-load lots give $85 to the ton, the ore showing richer as progress from the surface is made. A large force of men is at work day and night on this mine. The Manhattan is another claim owned and worked by this company, and is making an excellent showing at the present time. A large quantity of ore in the ore-house ready for shipment showed it to be rich in copper and galena, carrying a large percentage of silver.

The Ypsilanti Mining Company, located near the Great Eastern, is showing up well. A force of 30 men is now engaged day and night, and with the most satisfactory results. A large amount of ore is shipped daily for treatment. This property has been recently purchased.

Digitized by Google

The Bullion Prince Mining Company is working day and night-shifts on its cross-cut tunnel, run to cut the Brooklyn and Tropic lodes, which have been found to be valuable by sinking shafts. The ore is galena and gray copper, carrying silver. A mill-run of ore taken from the Brooklyn shaft near the surface gave a value of $44 per ton at the smelting-works at Golden. These lodes will be cut by the tunnel at a depth of over 300 feet, and it is expected large ore-bodies will be developed when the Brooklyn lode is reached, which is now only a few feet from the breast of the tunnel.

The Lisbon Mining Company has a claim in the Whale Extension, so called on account of its being an extension and next adjoining the famous Whale mine. The ore shows at the surface, and only a slight excavation disclosed a solid pay-streak of galena and silver from four to six inches in width.

The Snake River Mining Company has a shaft 100 feet deep in the Rosalie, with tunnels running into the mountain from the shaft, from which shipments of ore have been made of satisfactory value to the owners, who are preparing to work the properties on a much larger scale than before. The ore is free-milling, showing silver only, and is easily worked. The smelter at Argo gives mill-runs of 61 ounces to the ton in ore taken less than 25 feet from the surface.

FANNY BARRET.—The large caves lately discovered in these workings are not in a proper condition to thoroughly explore; consequently but little is as yet known regarding the real mineral value of their contents. Large bodies of iron exist in every section yet examined, and it is thought that when they have been thoroughly examined in all their openings, some valuable mineral will be found.

PITKIN COUNTY.

TAM O'SHANTER & MONTEZUMA.—For some weeks past, these mines have been shipping largely and regularly to Cañon City. Recently, Governor Tabor leased the Ashcroft, formerly the Brooks & Bethune smelter, and arrangements were made for reducing the product of the mine near the premises. Metallurgists have been on the ground, and pronounce the project practical. The mines are capable of producing fifty tons a day, and able to keep the works in blast. The reduction of the ore, it is said, can be effected a great deal cheaper at the mine than at Cañon City, including freight on ore.

SUMMIT COUNTY.

SILVER WAVE.—A rich strike of sand carbonates was recently made in this mine on Battle Mountain. The ore-body is between sixteen and seventeen feet in thickness, and runs nineteen ounces in silver and 75 per cent in lead.

DAKOTA.

CALEDONIA.—The superintendent reports for the week ended September 2d: Ore produced, 300-foot level, 1050 tons; shipped, 595½ ounces of gold; value, about $10,250. East cross-cut on 400-foot level has reached hanging-wall; work discontinued in this direction. The south drift is in 5½ feet.

ESTRELLA DEL NORTE.—The clean-ups are yielding very satisfactory returns, and, according to local papers, fully justifying the high opinion entertained regarding those properties.

FATHER DE SMET.—The superintendent's report for the ten days ended September 1st shows: Ore extracted from first level, 1200 tons; second level, 1200 tons; third level, 620 tons. Ore milled, 2970 tons. Golden Gate, south header, second level, in 24 feet. On August 21st, the total length of header was 19 feet, instead of 20 feet, as reported. Contract work stopped, header being run on company account.

IRON CITY.—W. E. Fulton, who recently went to Deadwood to examine the silver mines of the Iron City Mining Company, reports that they are valuable properties. General Manager Porter has been removed for mismanagement, and the mines will be further developed.

IDAHO.

The Willoughby, Clifford, Geneva, and Euclid claims have been sold to an Ohio company.

BULLWACKER.—An experimental run of this ore was made recently. A sample lot of about 15 pounds was put through the furnace. The result was two bars of base bullion weighing about seven pounds, and assaying at the rate of 290 ounces of silver per ton.

QUEEN OF THE HILLS.—The ore of this mine is very bright and pure galena, going about 75 per cent lead and 104 ounces silver. A new strike was made recently in the tunnel 225 feet from the mouth, and at a vertical depth from the surface of 150 feet. The vein, where struck, and on which some drifting has been done, is in width from twenty to forty-two inches, varying in different places. Besides this width of solid galena, there are eighteen inches of second-class ore. This strike is in solid ground, and is of so much importance that the property is looked upon as being worth double what it was estimated at, and was offered for it ten days ago, when parties wanted it at $25,000. It is near the Minnie Moore mine, and is supposed to be similar in quality and extent.

MEXICO.

SANTA BARBARA MINING DISTRICT.

The Chihuahua *Enterprise* speaks of this district as follows:

Among the principal mining districts of this State, Santa Barbara takes a foremost place. The ores are all low, hardly any going beyond three hundred dollars per ton, and as low as twenty dollars. All the silver is carried by the carbonates and sulphurets of lead. To work these ores, a large concentrating-mill is erecting by the Tecolote Silver Mining Company, of Harrisburg, Pa., which acquired by purchase three mines, Tecolote, Tecolotes de Abajo, and Santa Maria de la Bufa. About one and a quarter miles from the mines, the mill is building, and of the railroad from the mines to the mill, 855 feet. As the property is situated on a very high mountain, in fact, the principal one of the district, all the ore to be milled can be taken out of the mines by tunnels, and no money will have to be spent for hoisting and pumping water. Two hundred and sixty-six feet of new tunnels have been run already in the vein, producing ores daily, and 270 feet of cross-cut tunnel, half-way up the mountain. The mill machinery and rails are already on the road.

MICHIGAN.

The following is the product of the mines named for the month of August:

	Tons.
Calumet & Hecla	1833
Quincy	332
Franklin	183
Atlantic	166
Allouez	111
Pewabic	55
Huron	53
Peninsula	51
Copper Falls	39
Grand Portage	39
Hancock	36

Mr. Edward Ryan has purchased 39 acres of land on Pilgrim River at its mouth, for a stamp-mill site, in connection with the valuable copper disclosures he is interested in lying to the southwest, near Six-Mile Hill, on the Ontonagon road. The Houghton *Mining Gazette* says that one of the leading advantages of this location for reduction-works consists in being able to "flume" water from Pilgrim River into a mill for mineral dressing purposes, thus saving the cost of pumping, which is an expensive item. Mr. Ryan has also organized a corporation, called the Houghton & Rockland Railroad Company, for the purpose of furnishing rock transportation facilities from the mining lands he is handling to the lake shore at Pilgrim River, and extending the road along the mineral range to Ontonagon County, if developments in the future out that way warrant its construction.

ANDERSON.—Work at this property has recently been attended with most gratifying results, the ore taking a sudden change for the better, being now almost entirely free from the bunchy quartz which has thus far appeared. The shaft is now down 115 feet in the ledge on the foot-wall side of the vein, and if the ore continues to improve as it has in the last four feet, the shaft will be sunk but a few feet farther, when a drift will be run across the vein to further determine its value.

CALUMET & HECLA.—The improved iron jig will soon be put in the place of the wooden jigger in the dressing-mills of this mine.

CONGLOMERATE.—The extensive surface improvements on this mine are now well in hand. The new dressing-works, which embrace one of the most complete stamp-mills on the lake, will be ready to go into operation in a month or so. The railroad from the mine to the dressing-works will be in running order by the first of October.

EMMET.—This company has decided to sink another shaft 1000 feet to the northeast of the one now going down, and which will be in swampy ground. It is expected this work will require about two years to see its completion.

LAKE CHICAGOAN.—The mine has been unwatered and mining operations resumed.

MILWAUKEE.—It is probable that work will be resumed shortly. Arrangements are in progress whereby the question of royalty will probably be adjusted to the satisfaction of all parties concerned. The new rate will probably be 40 cents per ton.

OSCEOLA.—Developments in the old Osceola mine, on the deposit lying immediately west of the conglomerate, continue promising, and the openings afford considerable copper considering their extent.

PENDILL.—What was left of the effects of this mine has been sold recently to satisfy the claims of creditors. The old location will be used by the Detroit, Mackinac & Marquette Railroad Company as a depot site.

MONTANA.

BEAVER HEAD COUNTY.

HECLA CONSOLIDATED.—A committee of stockholders, consisting of Hon. Thomas A. Hendricks, Judge E. B. Martindale, Hon. John C. Wright, and Hon. A. D. Lynch, who recently made a minute examination of the property and works of the company, make the following report to the board of directors regarding the management of Superintendent Knippenberg: The general management of the property, under Mr. Henry Knippenberg, is characterized throughout by intelligence, integrity, and economy. He has surrounded himself by the best class of men that could be collected in a large mining enterprise, and has succeeded in instilling into each the desire which is uppermost in his own mind, that is, to promote the interests of the stockholders. While we can not enter into details, we think it is proper to say that the company is peculiarly fortunate in securing the services of Mr. Knippenberg as general manager, and of Mr. James Parfet as superintendent of the mines. Mr. Parfet has displayed great skill in opening up the mines, and great energy and sagacity in keeping his reserves in sight, so as to be able at all times to point out the ores required to keep the concentrator and smelter employed, for a full year in advance, without additional development.

GALLATIN COUNTY.

EASTERN MONTANA MINING AND SMELTING COMPANY.—The smelter has started up on custom rock and is making weekly shipments. It is under lease to the Wills Mining and Smelting Company, and will be run regularly.

GREAT REPUBLIC.—The water-jacket smelter now erecting at Cooke City, to treat the ores of this and other mines owned by the company, will have a capacity of forty tons.

JEFFERSON COUNTY.

News from the mines around Boulder Valley shows the following:

ALICE.—While running an open cut on this claim, to find the vein before sinking a shaft, ore was found which returned 199 ounces of silver to the ton.

AMAZON MINING AND SMELTING COMPANY.—Some good ore is taken from the Lexington, the property of this company. The company's machinery has arrived in Helena, and will be sent to the mines at once.

BOBTAIL.—This mine is developed by a shaft 70 feet deep and another shaft 25 feet deep; the pay-streak is two feet wide, and produced very fine carbonates of lead on the surface; at the bottom, the ore is mostly galena. The ore is of a very good grade in lead and melts very easy. Several lots have been shipped, and yielded from 50 to 300 ounces in silver to the ton.

EQUITABLE.—The company owns some very promising prospects. Most of the work is done on the Willie location. The shaft sunk is now 55 feet deep, and the ore produced shows highest assays.

JOSEPHINE.—This claim, owned by the same parties as the Bobtail, shows about the same character of ore. The shaft is 25 feet deep, and at the bottom the vein proves to be seven feet wide.

STOCKTON.—A body of ore six feet wide, with only one wall exposed as yet, has been struck in the new shaft at a depth of 23 feet. The ore consists of a streak of galena about one foot thick, a sample of which assayed eighty-six ounces in silver and $35 in gold to the ton, the other five feet consisting of good concentrating ore. This lode is opened by four shafts, developing the vein for a length of over 200 feet, and there is good ore in every one of the shafts. A tunnel is now driving which will tap the vein 125 feet below the surface. The tunnel is 60 feet in, with about 90 feet more to run.

LEWIS & CLARKE COUNTY.

GLOSTER.—The work at the mine is progressing rapidly. The pan-sills are in for the new pan-mill, the grading is all completed, and the foundation-walls of the enormous building (200 by 60 feet and 80 feet high) are all laid. The excavations for the foundation for the large 300 horse-power engine are making. The entire sixty-stamp mill with twenty-four pans and twelve settlers, crushing 180 tons of ore per twenty-four hours, will be running by the 1st of November. The contractor has begun work on the shaft, and expects to sink 100 feet within ninety days. This shaft will be 18½ by 7½ feet, with three compartments.

SILVER BOW COUNTY—SUMMIT VALLEY DISTRICT.

CLARK'S FRACTION.—The developments at this mine, which lies between the Alice and Magna Charta properties, continue to demonstrate the value of the old Rainbow lode. The 40-foot ledge in the face of the 80-foot cross-cut has been fully described in previous reports. A drift has been run from the east 300 feet of the Alice, which has reached a point directly beneath the 80-foot workings, and a three-foot ledge of high-grade ore has been uncovered. The assays average 100 ounces, and several samples went from 280 to 530 ounces. The drift will be run through the Fraction 221 feet to the Magna Charta line, when cross-cutting and uprising on the ledge will be commenced.

SHONBAR.—The principal work just now is sinking the shaft for the 300, 400, and 500-foot levels. An additional pump has been put in at the 230, which keeps the water clear.

TRAVOLNA.—W. A. Clark has purchased S. E. Larabie's interest in this mine, in which the first discovery of silver in Summit Valley District was made by William Farlin in 1875. Mr. Clark is preparing to begin active operations in the mine.

NEVADA.

ELKO COUNTY.

INDEPENDENCE.—The superintendent's annual report shows that during the past year 267 17-20 tons of ore, averaging $322.88 per ton, have been extracted and milled. The Navajo Mining Company, having the mill in use, milled the ore

Digitized by Google

at the rate of $25 per ton, net cost, and worked it to 93 per cent of the battery assay. Settlement was made at that percentage. We received and shipped to the Anglo Bank of California bullion to the amount of $62,910.45; and after deducting bullion discount, on the balance of the bullion, and paying for the milling of the ore, we received from the Navajo Company in coin $8472.07. The ore-seam averaged very small, but the grade of ore ran unusually high. This ore was extracted above the 300 level, and considerable work has been done in the same locality without discovering any more ore. Above this ore-chute, drifts and cross-cuts have been driven to the extent of about 200 feet, and a cross-cut on the level extended west a distance of 612 feet. Nothing of value was developed in these workings. The west cross-cut passed through a very hard formation, and the ventilation being very bad, progress was slow, and the work necessarily expensive. The main drift north on this level has been extended during the past year 380 feet. The formation encountered looks very favorable for ore; and in time, cross-cuts will be extended to the right and left, to thoroughly prospect the ground then opened. On the 400 level, a prospect-drift has been driven south 928 feet. It will be continued until it has reached a point under No. 1 shaft at the south end of the mine, which has been sunk to the depth of 190½ feet. At this point, connection with the shaft by an uprise will be made, thereby securing good ventilation. At present, a fan is kept running constantly, to enable us to work in the drift. As soon as this connection is made, cross-cuts can be extended at all favorable points. About 400 feet from the face of the drift, one cross-cut has been started east, and is in 105 feet, and one west advanced 18 feet. In this distance, nothing of note has been encountered. Considerable work has been done in repairing and retimbering old drifts, necessary to be kept open, in view of future workings. Although no development of any consequence has been made the past year, the prospects are flattering for good results, when cross-cuts are extended from the drifts now driving north and south on the 300 and 400 levels.

NAVAJO.—The following is a summary report by the superintendent of the work done during the past year: Although some bullion was shipped prior to my last annual report, no estimate was made of the results of the experimental mill-run, conducted for ten days previous to that date; but the results from the same will now be included in the total estimate of the milling done for the past year.

The mill-run covers a period of 321 days, of which the actual running time was 309½ days; showing a loss of 11½ days, including all stoppages. Milled 3955·6 tons of Navajo ore, and 282¼ tons of custom ore, making an average crushing of 13⅜ tons of ore per day. The average battery pulp-assay of the ore from the Navajo mine was $199.40 per ton, and was worked to 92·6 per cent of the battery assay; custom ore averaged $332.10 per ton, and was worked to 92 per cent.

Shipped bullion on customers' account to the amount of $64,863.42. On Navajo account, to the Bank of California, from Navajo ore $730,379.38; from custom ore, $21,549.37; from profits on custom ore, $2206.58, making a total production in bullion of $818,898.75 (assay value) from the 21st July, 1882, to the 7th June, 1883; of which amount $729,874.58 was shipped during the fiscal year on company account.

The quantity of ore crushed for a battery of ten stamps, and the percentage to which it was worked, has been unusually satisfactory. The condition of the mill for the last half of the run added materially to the cost of reduction, and the repairs required on the engine necessitated a suspension of work for a considerable length of time. The mill is now repairing, and, when completed, will materially reduce the cost of milling. Since the Grand Prize works were destroyed by fire, we have been without a supply of water. Will now make connection with the Navajo works, in anticipation of a partial and perhaps a sufficient supply when water is encountered on the 650-foot level.

During the past year, the shaft has been sunk 330 feet, making its total depth 680 feet. The formation encountered was extremely hard and difficult to work, requiring ten months' steady work to sink it to its present depth.

The ore reserves on the 650, 500, and 450 levels are sufficient to supply the mill for a considerable length of time, although the grade of ore may be as much lower, as that milled the past year has proved to be higher than it was placed at in my estimates of last year.

As soon as the compressor is in working order, pipes will be laid to conduct compressed air to the various points where work is in progress, and power drills will hereafter be used in place of hand-drilling, which we expect will result favorably in an economical point of view, as well as speedier work, of which there is no doubt, as the rock encountered in this mine is extremely hard, and, by hand-drilling, progress necessarily slow and expensive.

Prospect-work has been carried on to an extent to readily determine, at a nominal expense, the value of as many new levels as have been explored during the past five years.

WHITE PINE COUNTY.

MARTIN WHITE.—At the annual meeting, held in San Francisco recently, the following report was presented:

We have run on the upper level 286 feet of drifts. In doing this, we have extracted 120 tons of ore, assaying from 30 to 200 ounces and over. One half of a ton that was put in sacks will assay 5000 ounces per ton. We have also found a good body of ore, into which we have drifted twenty feet, and the ore taken out will assay 80 ounces altogether. The vein is wider than the drift, but I do not know how much. From the location of this ore and its character, I think it is the most valuable body of ore that has been opened within the year. We have worked out stope No. 1 on the 160-foot level, from which were extracted about 400 tons of ore, assaying 30 ounces and upward, besides a large amount of second-class ore that will be worked at a profit some future time. We are now working in two places on this level with fair promises as to ore. We are also working on a small body of ore in the Mountain Pride tunnel that promises well, the ore assaying over 30 ounces. This body or vein has been drifted on about thirty feet. Some of the distance, the drift cuts all the ore; in others, the ore extends beyond the sides or limits of the drift. Although small, this is the best find of ore that we ever had on this level in my estimation, as it is directly under the best ore-bodies of the upper levels, and it will probably connect with them.

The secretary's report shows that there is $33,513.30 worth of supplies on hand and ore extracted valued at $44,182.30.

MINERAL PATENTS GRANTED BY THE UNITED STATES LAND-OFFICE.

The following mineral patents have been granted by the General Land-Office since the last date:

ARIZONA.

TUCSON DISTRICT.

Solomon Warner, Santa Tomas lode. Horseshoe Mining Company, Alta lode. Merrimac Silver Mining Company, Lucknow lode. Heirs of Jacques Traves, deceased, Mariquitta lode. Joseph McCarter, Cuprite lode. Philip Corbin *et al.*, Hendricks lode.

CALIFORNIA.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Sept. 14.

The mining market this week has shown considerable activity, and better prices have prevailed. The chief interest has been centered in the Leadville stocks, which have been quite active and strong. This is owing to several important strikes having been made in the district, and the prospects of early dividends being declared by some of the companies having mines there. Amie leads in the transactions, and, as a dividend has been declared, it sold quite strong. Little Chief was also very strong under reports of a rich strike. The fancy stocks have come in for a good share of the business done, but about the only one which has shown any change in price has been Robinson, which has been weak. Eastern Oregon has been allowed to drop back to its normal figures, the "bull" clique evidently becoming tired of booming it. The total number of shares aggregates 165,926 shares, as against 133,810 last week.

The Comstock shares were very moderately dealt in at about steady prices. California was quiet and a little weak, selling from 30@24c. Consolidated Virginia was also quiet and irregular; it sold from 56@53@54c. Sierra Nevada was weak, under a very small business, selling from $5.50@$4@$4.25. Union Consolidated was quiet and steady at $4.90@$5. Ophir sold at $4.25; Gould & Curry at $3.25; Hale & Norcross at $4.70; Yellow Jacket at $3; and Best & Belcher at $4.40. These stocks all record but one transaction each. Sutro Tunnel was very quiet and steady, selling at 19c.

The Leadville stocks show a decided improvement both in the dealings and prices. This is owing to several rich strikes recently made in this district. Amie was very active and quite strong, selling from 13@23c. This company has recently declared a dividend, the first in several years. It is rumored that this dividend was declared by the present managers, in order that they might retain the control of the company, as there has been a decided disposition on the part of some of the stockholders to oust them from the management. Chrysolite was also strong, with a fair business, selling from $1.10@$1.25@$1.15. Dunkin was quiet and steady, selling from 32@36@35c. Breece sold from 19@18c. Iron Silver was quiet and steady at $3.10@$3@$3.05. A rich strike has been made in the Moyer shaft of one of this company's mines, and it is reported that a dividend will soon be declared. Leadville was quiet and steady at 32@30c. Little Chief was active and quite strong, selling from 47@61c. A rich strike is reported to have been made in this mine. Little Pittsburg was also strong, with a small business, selling from 57@63c. Climax sold from 10@8c.; the business was small.

The Bodie stocks were quiet and steady. Bodie Consolidated was quite strong under a small business, selling from 70@95c. Standard was a little weak, under small transactions, selling from $5.50@$5.25. Bulwer sold at 70c. North Standard was quiet and steady at 7@10c.

The Tuscarora stocks were very quiet at steady prices. Navajo was quiet at $2.50. North Belle Isle was moderately dealt in at steady prices, selling from 47@45c. Elko Consolidated suffered a slight decline from last week, under an active business; it sold from 12@10c.

In the miscellaneous list, Alice was quiet and steady at $2.10@$2.15. Eureka Consolidated was quite strong, with a fair business, selling from $7.13@$7.63. Green Mountain was quiet and steady at 70c. Hall-Anderson was fairly dealt in and was steady; it sold from $1.25@$1.15. Horn-Silver was quiet and strong, selling from $7.13@$7. This mine is reported as looking very well. The annual meeting of stockholders will soon take place in Utah. Northern Belle was moderately active and was a little weak; it sold from $6.18@$5.88. Robinson Consolidated was very active and weak; it sold from 47@37@38c. Sierra Grande was very quiet at steady prices, selling at $1.05.

Alta-Montana was quiet and steady at 4@5c. Barcelona was active and irregular, selling from 34@49@40c. Central Arizona was quiet and strong, selling from 25@30c. Eastern Oregon was quite weak from its recent strong prices, with a small business, selling from 40@46c. Oriental & Miller sold from 12@10c., with small transactions. Sonora Consolidated was quiet and steady, selling from 24@30@27c.

The Secretary of the Tombstone Mill and Mining Company writes us that the company has just completed the payment of another installment of $25,000 on its funded debt; that the mill and furnace are now running regularly; and that the mines promise well for the future.

MEETINGS.

Dunkin Mining Company. Office of the company, Leadville, Colorado. Election of trustees and the transaction of such other business as may come before the meeting, October 12th, at twelve o'clock M.

The Horn-Silver Mining Company. Office of the company, Frisco, Utah. Annual meeting of stockholders and election of trustees on Tuesday, October 12th, at twelve o'clock M.

Little Chief Mining Company, No. 137 Broadway, New York City. Annual meeting of stockholders and election of trustees, October 2d, from twelve o'clock M. to two o'clock P.M.

The Sierra Grande Mining Company, the Sierra Bella Mining Company, the Sierra Apache Mining Company. Office of the company, Lake Valley, Mexico. Annual meeting and election of trustees, September 26th.

The Yedras Mining Company, No. 62 Cedar street, New York City. Special meeting of the stockholders Friday, September 21st, at twelve o'clock noon.

DIVIDENDS.

The Amie Consolidated Mining Company, of Colorado, has declared a dividend of five cents per share on the capital stock, payable at the office of the company October 2d, 1883. The transfer-books will close September 24th, and reopen October 10th, 1883.

The Barclay Coal Company, of Pennsylvania, announces a semi-annual dividend of three per cent, payable September 15th.

The Holyoke Mining Company, of Idaho, has declared a dividend (No. 12) of two per cent on the capital stock, payable September 18th.

The Homestake Mining Company, of Dakota, has declared a dividend (No. 61) of $50,000, payable September 25th. Total dividends to date $2,212,500.

The Little Chief Mining Company, of Colorado, has declared a dividend of $20,000, or ten cents per share, payable October 9th.

The Oro Grande Mill and Mining Company, of California, has declared a dividend of $24,000.

The Plymouth Consolidated Mining Company has declared a dividend of fifty cents per share.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows for the week:

During the latter part of last week, there was a dull dragging market, in the neighborhood of $1.08 for petroleum. On Monday morning, the announcement was made that the monthly statement for August of the United Pipe Line Company, instead of showing an increase of stock over the preceding month of about 80,000 barrels, showed a decrease of 197,000 barrels in gross stocks. It has been six or seven years since the surplus was reduced in any one month, and this fact was used as a pretext for manipulating the market to higher prices, forcing the shorts to cover and every body to go long. Under the influence of this statistical showing, and the advance to 8⅝ of refined oil, free buying was stimulated and the bulls were triumphant.

On Wednesday, the market opened at $1.16, sold up to $1.16¼, the highest point this month, when a general selling movement developed, carrying prices down to $1.12½. Meanwhile, the price of refined was reduced to 8⅛@8¼, and the fact became apparent that the "runs," or receipts, exceeded the shipments 23,000 barrels, and the decrease in gross stocks was due to the Pipe-Line Company charging off on its books over 200,000 barrels of oil. This was really deceptive to the trade until the figures were analyzed and the explanation given. Now, however, up to the 11th inclusive, the shipments nearly exceed the deliveries about 150,000 barrels, and September will probably show a real decrease in oil on hand. The charters for export are large, being at the rate of 55,000 barrels daily this month, against 49,000 in August and 39,000 in July.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, September 13.

The market for copper stocks has been quite strong the past week, and orders to purchase some of the best mines have resulted in an advance of prices, while but few stocks have been sold and but a limited amount offered. There is no change in quotations for ingot copper; but there is a firm tone to the market which, no doubt, strengthened the belief that some of the stocks have been selling below their value, and at present prices are undoubtedly low, and warrant an advance before the winter season sets in. Quincy has been in most active demand, and although less than two hundred shares are reported as sold, the price has advanced from $46@$53½, closing, however, at $52 bid, $53 asked. Calumet & Hecla advanced to $245, a gain of three points. Very little stock is offered, and it is difficult to fill orders at current prices. Franklin advanced from $9⅞@$11, with sales of 300 shares. This stock has been unduly depressed, and ought to sell higher. The non-payment of the expected dividend has, no doubt, had its

Digitized by Google

influence on the stock. Osceola is steady at $18, with but little stock in the market. Atlantic advanced $\frac{1}{4}$, with sales at $10\frac{1}{4}$. Huron was strong in the early part of the week, at $1\frac{7}{8}$, without bringing out the stock; but later, from some reason which we could not learn, a block of 500 shares was put on the market and offered down to $1\frac{1}{2}$ before finding a purchaser, and to-day $1\frac{3}{8}$ was the best bid. Pewabic sold at $3\frac{1}{8}$; but there is not much demand for it, as the outlook is not so promising as its friends could wish.

In silver stocks, there is very little doing. Bonanza Development was the most active, and advanced from $1\frac{1}{8}$@$1\frac{7}{8}$ on sales of 750 shares. Catalpa sold at 37½c., and very dull. It is reported that the mine is just about paying expenses, and not much outlook for a dividend this year. Sullivan advanced from 87½@97½c., at the Mining Board, where the stock has been quite active. Sales on buyer's option, 30 days, were made at $1.02½. Bowman Silver has ruled heavy for the week, and sales reported at 16c., and but little doing in it. Massachusetts & New Mexico, steady at 5@6c, the latter on buyer's option. Dunkin sold at 30c., but to-day 33c. was bid, 37½c. asked.

3 P.M.—There has been literally nothing doing in mining stocks to-day at the regular Stock Board, and very few sales at the Mining Exchange. We giv closing quotations: Calumet & Hecla, $245 asked Franklin, $10½ bid, $11⅛ asked. Huron, $1¼ bid. Osceola, $17½ bid, $20 asked. Pewabic, $3 bid, $3½ asked. Quincy, $49 bid, $52 asked. Allouez, $1¾ asked. Atlantic, $9 bid, $11 asked. Silver Islet, $2 bid. Bonanza, $1¾ bid, $1⅛ asked. Catalpa, 35c. bid, 37½c. asked. Sullivan, 90c. bid, $1 asked.

METALS.

NEW YORK, Friday Evening, Sept. 14.

Copper.—The firm tone repeatedly referred to in recent issues continues. There are few sellers of Lake copper and a limited number of buyers, but better prices are paid. We quote 15⅛@15¼c. Other brands are slightly higher, 14⅛@14¾c. according to brand.

England is a little better, cabling £63 10s. for Chili Bars.

The following are Messrs. James & Shakspeare's statistics for the month of August:

	Aug 1 to 31. Imports. Tons.	Deliveries. Tons.	
Fine foreign, chiefly Australian.	699	1,152	London.
Chili Bars	715	1,378	Liverpool and Swansea.
Chili Ingots	350	335	
Chili In ores and regulus	Nil.	Nil.	
American	1,390	1,430	
Spanish precipitate and sundries.	3,074	2,453	
Totals, England	6,228	6,748	
American	670	710	France.
Chili bars, ingots, and Barilla	2,394	2,496	
Sundries	35	35	
Total, England and France	9,327	9,989	

	Stocks. Aug. 31 Tons.	July 31. Tons.	
Fine foreign, chiefly Australian	4,078	4,531	London.
Chili Bars	23,334	23,997	Liverpool and Swansea.
Chili Ingots	451	436	
Chili In ores and regulus	1,813	1,813	
American	138	178	
Spanish precipitates and sundries	4,457	3,836	
Totals, England	34,271	34,791	
American	390	430	France.
Chili bars, ingots, and Barilla.	2,047	2,149	
Sundries	30	30	
Total, England and France	36,738	37,400	
Advised by mail and telegram:			
Chili	11,207	11,147	
Australian	900	1,000	
Stock and afloat, gross total	48,845	49,547	

The pith of the statistics is given in the following figures for the first eight months of the year:

	Jan. 1 to Aug. 31. 1883. Tons.	1882. Tons.	1881. Tons.
Imports	60,421	51,353	49,789
Deliveries	58,810	53,609	53,246

This shows a very heavy increase in the imports, and a less marked growth in the deliveries.

Tin.—There has been considerable speculative activity, London holding at £94. We quote spot values: Straits, 21c.; Australian, 21⅛c.; Billiton, 21⅛@21⅝c.; and Banca, 21¾c.

Lead.—There has been some activity, and the happenings of the past few days have borne out the views which we print editorially to-day. There have been sales of 300 tons, ordinary Germania and other Western lead, at 4·32½c.; and as we go to press, it is rumored that an additional lot of 300 tons of Germania Common has been disposed of at a slightly lower figure. There have also been sold 180 tons of Germania Refined and 100 tons of another brand of Western Corroding at 4·35c., both to one white-lead manufacturer, while the common lead has been pretty widely distributed. These sales indicate clearly that, as soon as any effort is made to place even moderate quantities of lead, the market swerves under it. So far as the Western holders are concerned, their policy is apparently to keep our market here high, in order that its quotations may serve as a basis for the many minor transactions in other manufacturing cities, which take their cue from us. It is evident that, if any attempt were made to force a larger quantity on our market, it would promptly fall off under the weight. We quote 4·33½c. for Common, and 4·35c. for Refined.

From St. Louis, Messrs. John Wahl & Son wire us to-day:

The market is a little easier. We record sales of 160 tons of Refined at 4·08c. and quote Common nominally 4@4·02½c.

Messrs. Everett & Post telegraph from Chicago as follows:

For both Common and Refined, there is a fairly active demand, and the prices are stiffly held, offerings being only moderate. Otherwise, there is no change of any description, quotations being nominally 4·10 4·12½c.

Spelter.—The firmer feeling still prevails, and it would be difficult to shade 4½c. for ordinary Western. Silesia is held at 5@5⅛c., without any business doing.

Antimony.—There is nothing new to report in this market.

BULLION MARKET.

NEW YORK, Friday Evening, Sept. 14.

Nothing worthy of comment has occurred in the silver market abroad or here since our last week's ratings.

Date.	London. Pence.	N. Y. Cents.	Date.	London. Pence.	N. Y. Cents.
Sept. 8	50⅝	109⅞	Sept. 12	50⅝	110
10	50⅝	109⅞	13	50⅝	110
11	50⅝	110	14	50 11-16	110

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended September 14th, as compiled from various sources, amounted to $181,300, as against $193,000, reported for the previous week. The receipts from January 1st, 1883, to date are $7,988,274.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended September 8th	$450,590
Corresponding week last year	170,000
Since January 1st, 1883	9,828,766
Corresponding period last year	43,626,267

Imports.

Week ended September 8th	$225,480
Corresponding week last year	28,311
Since January 1st, 1883	10,466,971
Corresponding period last year	2,607,338

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, reduced the bank's minimum rate for discount from 4 to 3½ per cent. During the week, the bank gained £140,000 bullion, but the proportion of its reserve to its liabilities was reduced from 47 11-16 to 46¼ per cent, against 39 3-16 per cent at this date a year ago. September 13th, the bank gained £29,000 bullion on balance. The weekly statement of the Bank of France shows losses of 2,575,000 francs gold, and of 4,475,000 francs silver.

Purchase of Silver Bullion.—The Treasury Department purchased 296,000 ounces of fine silver to-day for the mints at Philadelphia, New Orleans, and San Francisco.

" " Aug.	17,746	5,772	6,851	7,532	37,901

American Pig.—We have had occasion to verify the statement of the condition of the market made in our last issue. What should be the busy season has set in, and thus far it shows no signs of meeting the expectations of makers. September and October are the months in which the largest amount of business is closed, and yet the orders on the books are few and limited. There is no doubt that consumption has fallen off more largely, particularly in some quarters, than was believed, and the theory that consumers are waiting until deliveries on contracts made in the summer are completed will not fully account for the dullness. Such season contracts were made later this year than in ordinary years, but they were also very much lighter.

Transactions during the week have been on a moderate scale. We quote No. 1 Foundry, $21.50@$23; No. 2, $19@21, according to quality; and Gray Forge, $18.25@$19.50, all at tide-water. Bessemer Pig is lifeless, and Spiegeleisen is quiet at $30.50@30.75 for 20 per cent. Lower grades are dull at @$25.50.

At the Exchange, the following sales were reported the market closing weak and unsettled :

Saturday, 100 tons, No. 1, November, $21.87½ ; 100 tons No. 1, November, $21.75 ; 200 tons No. 1, January, $22.25. Monday, 100 tons No. 1, November, $21.87½ ; 100 tons No. 1, December, $22 ; 100 tons No. 1, January, $22.25 ; 100 tons No. 1, February, $22.25. Tuesday, 100 tons No. 1, December, $21.75 ; 600 tons No. 1, January, $22. Wednesday, 500 tons No. 1, January, $21.87½. Thursday, 100 tons No. 1, February, $21.87½ ; and to-day, 300 tons No. 1, February, $21.87½.

Scotch Pig.—Though arrivals have been light, there is a growing tendency to send them to store. A part of the pig coming in is delivered on contracts still running, while only a comparatively small proportion is brought in by outsiders, who are apparently giving up the business in disgust. Freights are slightly higher.

We quote ex ship : Coltness, $23.50@$24 ; Langloan, $23@$24 ; Summerlee, $23 ; Dallmellington, $20.50@$21 ; Eglinton, $20@$20.50 ; and Glengarnock, $22 $22.50.

At the Exchange, the following lower cable quotations were received : Coltness, 59s. ; Langloan, 58s. 3d. ; Summerlee, 56s. 6d. ; Gartsherrie, 56s. ; Glengarnock, at Ardrossan, 54s. 9d. ; and Eglinton, at Ardrossan, 47s. 9d. Warrants to-day were 46s. 5d.

Steel Rails.—We have been unable to learn that any large orders have been placed, as rumored. The one in the market, referred to in these columns before, was for June, July, and August delivery, the section being a difficult one, and the inspection severe. This lot has not yet been placed, according to good authority. For small lots, early delivery, the quotation remains $37.50 at mill.

Old Rails.—No business of magnitude is reported. We quote $23.50 for Ts.

Scrap.—Beyond sales of small lots from yard, there is nothing to note. We quote $23@$23.50 ex ship.

Philadelphia. September 13.

There are indications that the lull in the demand for iron, which has lasted for several weeks, will soon terminate in a healthful activity. This is indicated by the number of inquiries for forge and foundry iron, and offers made a little below makers' terms. A number of buyers of forge irons have been in the market to buy enough for sixty days ; but the general run of buyers are still purchasing for current requirements and trusting to future output to bring lower prices. This is becoming more and more dangerous, on account of the number of heavy sales which have recently taken place. Good brands of Forge are scarce, and, during the last few days, consumers have been paying $18.50@$19 at furnace, but there is still a good deal of iron to be had at $18. There are plenty of offers in hand at $17.50, but nothing but an inferior iron can be had at that price. Inquiries for 1000-ton lots of Forge are made, with offers at $17@$17.50, but very little business of this kind is done as yet. It is probable that, during the next week or ten days, buyers will decide what they will do, and pay about $18 or $18.50. Foundry irons are selling at $22@$23 for No. 1 and $19@$21 for No. 2, averaging about $20 and $22 for the two numbers. If all the offers made were accepted, business would be active. Makers feel themselves safer now than two weeks ago. The restriction in production during the second quarter of the year is beginning to tell, and wise buyers are beginning to look for supplies before any decided upward tendency can manifest itself.

Bessemer is quoted as usual at $21@$21.50, without business of any importance. There are offers at less. Scotch iron is moving more freely, but in small lots. English iron is under inquiry, but no purchases have been made.

Muck Bars.—Sales of Muck Bars have been made at $33.50, with $34 generally asked.

Blooms.—A few lots of Charcoal Blooms have sold at $57@$58.

Merchant Iron.—Merchant iron is moving at 2·10@2·25c. The cutting of rates which has been going on for the past thirty days seems to be discontinued. There are fears of Western competition, and this leads to the naming of lower rates than would be named otherwise. For large lots, 2·10c. is taken, but 2·15@2·20c. are the usual prices.

Nails.—Nails are quoted at $3, and are quite active, but in lots smaller than car-load. Lots for export are selling at $2.90. Stocks are not large, and, if the West does not get too anxious to sell, the above figures can be maintained.

Plate-Iron.—Quite a number of small orders of 50 to 100-ton lots have been taken this week at 2·40@2·50c. for Common and 3@3·25c. for Shell, with Flange at 4@4·15c.

Structural Iron.—Structural iron manufacturers report an active inquiry for bridge iron, and orders for early delivery for building purposes. The mills are well supplied with business, and prices, in small lots, are firmer than usual, at 2·30@2·50c. for Tank. Beams, Channels, and Tees are unchanged. Inquiries for several hundred tons have been made, and the outlook points to a steady activity up to the winter months.

Sheet-Iron.—The sheet mills are all crowded with orders, most of them all for delivery during this and next month, and business is likely to be closed this week for November delivery. Prices are firm.

Wrought Pipes and Tubes.—This week's business was done between 70 and 75 per cent off for pipes, and boiler tubes 60 off in small lots. The aggregate of consumption is heavy.

Steel Rails.—No change has taken place in rails, although large transactions are said to be on the point of closing at or below $37. A large amount is wanted, and buyers seem to insist upon the acceptance of their own terms. Old rails are quiet with $23 bid, and offers at $24. Scrap is without change, and demand light.

Pittsburg. September 13.

The American Tin Plate Association has just issued a circular, which is distributed by thousands over the country, calling attention to the prostrate condition of that industry and the means of relief which that Association intends to advocate before the next Congress. All persons who favor the imposition of a protective duty are requested to send their names, addresses, and occupations, that they may be added to the list of names now under compilation. The Western Nail Association met to-day, and took the necessary and proper action for the protection of the interests of the nail trade. The demand for nails has fallen off during the past few weeks, owing to the completion of the contracts for building requirements, and considerable apprehension is felt as to the possibility of disposing of the output of the 2500 machines throughout the West. Stocks are slowly increasing, but the market has been tempted to make heavier purchases by concessions to $2.75 and $2.70.

The merchant iron trade is lacking in activity, because of the apprehensions in consumers' minds that the producing capacity is so far above requirements as to lead to competition which will yet depress prices below the exceptionally low limits of 1·80c., which is now named for large lots. Small lots are 1·90@2c. Producing capacity is working to about 80 per cent. The merchant steel mills are working to almost full capacity, and deliveries are made upon summer contracts throughout the West ; but the new fall business comes in very slowly.

Heavy concessions have been made on forge iron to secure business. Gray Forge is selling at $17.50@$18.50 ; No. 2 Foundry, $20 ; C. B. Charcoal, $33@$35, four months' time, and $26@$29, cash, according to quality. One thousand tons Muck Bar sold at $33.50. Wrought pipes and tubes are active. Pipes are selling at 75 per cent off list. Oil-well Castings, 43@45c. per foot. Two sales of American Ts were made at $24. Inquiries are out for English Ts, and Eastern buyers have orders for several thousand tons at fixed prices, which it is not probable will be filled for some time. The demand for Spikes is active at 2·60c. shaded. Track-bolts are 3c. Construction Iron, Plate, and Tank, are in active request, and mills are crowded with orders for sixty days.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Sept. 14.

Anthracite.

By energetic work, chiefly on the part of middlemen, the anthracite coal which comes to this market is taken care of. Buyers have not awakened from their lethargy, and the market drags along There is no accumulation of stocks, so far as we can learn ; but on the other hand, prices show no signs of materially improving. On the contrary, the trade has every reason to indulge in congratulations that coal has not followed the example of every leading industry of tending to materially lower figures. We have expressed our views concerning the best course to pursue to maintain this desirable state of affairs.

From the East, come discouraging reports. A correspondent writes us this week : "Hardly any coal has been sold." The low freights from Philadelphia give the shippers from that port an advantage equivalent to 25@30c., which the Boston agents of New York parties must meet.

Concerning the West, the special correspondent of *Coal* writes :

If, with the experience of the past week confronting them, there remain any operators in the coal market who maintain that an advance in circular rates necessarily means an advance, or even stiffening up, in selling prices, such benighted operators are simply past conviction to reason. Your correspondent has yet to meet with the first wholesale dealer or shipper in this market who honestly contends that the advance in the circular one week ago to-day has had the least effect either on the activity of the market or on prices. Anthracite is selling at just about the same rates as in June and July, and there is just about as much cutting in circular rates proportionately as then. Milwaukee is, if any thing, more of a thorn in the flesh of the Chicago trade than it was last year. A good proportion of the shortage in our supply of anthracite, as compared with that on hand a year ago, has been diverted to Milwaukee, that market having about 50,000 tons more, while Chicago has about 98,591 less, than one year ago.

To the iron trade, the following notes on coke from the letter of the Pittsburg correspondent of *Coal* will be of interest:

Coke remains at the price quoted last, your exchanges to the contrary notwithstanding. A statement has gone forth that "an advance to $1.10 has taken place." This of itself is vague. It is too low for foundry and a trifle high for furnace orders. The fact of the matter is, that coke is selling at $1.05@$1.10 for furnace orders, free on board, and $1.15@$1.25 for foundry and selected, and there has been no change for nearly two months. Manufacturers, however, talk of advancing rates 5 or 10 cents next month, dependent on the condition and prospects of the iron trade in the interim. The "pool" question excites more interest than the markets in coke just now. Appearances indicate that the present pool will be broken up and that the Vanderbilt line and the Baltimore & Ohio will be awarded a larger share of the trade which is now enjoyed by the Pennsylvania and its leased lines. If these lines can not agree on a new pool, so much the better for the coke men, who seem to sniff a cutting of rates in the near future. Crushed coke is inquired for at $1.75 per ton at the crusher. Its merits as a substitute for hard, at three times that price, are becoming yearly more recognized in the market. The scarcity of cars in this trade which existed a week ago has about ended, and shippers are not complaining on this score.

Bituminous.

We are informed that the recent troubles among the miners in the Clearfield region are over. There is a slight scarcity of cars there. In general, a little improvement in the number of inquiries is noted, though quotations remain at the low figures.

Horsford's Acid Phosphate.

Valuable in Indigestion.

Dr. DANIEL T. NELSON, Chicago, says : "I find it a pleasant and valuable remedy in indigestion, particularly in overworked men."

DIVIDENDS.

HOMESTAKE MINING COMPANY, MILLS BUILDING, 15 BROAD STREET,
NEW YORK, Sept. 12, 1883.

DIVIDEND NO. 61.

The regular monthly dividend of FORTY CENTS per share has been declared for August, payable at the office of the Transfer-Agents, Lounsbery & Haggin, Mills Building, 15 Broad Street, on the 25th inst.
Transfer-books close on the 20th.
LOUNSBERY & HAGGIN, Transfer-Agents.

THE CENTURY CONSOLIDATED MINING AND SMELTING CO. ; OFFICE, ROOM 56 TRIBUNE BUILDING.
NEW YORK, Sept. 14, 1883.

Notice is hereby given that a special meeting of the stockholders, for the purpose of amending the company's by-laws, will be held at the office of this company on Tuesday, October 2d, at 3.30 o'clock P.M.
By order, B. FRANK WOOD, Secretary.

G. E. RANDOLPH & CO.,
CENTRAL CITY, COLORADO,

Advertisers' Index xii

AFTER a comparatively long period of activity, the investment of Northern capital in Southern coal and iron lands has fallen off. A reaction has set in and the Southern States will now have to prove that the expenditure of large sums was fully warranted. The trade is one in which both the new-comers and the residents must develop all their energies.

PRIVATE dispatches received in this city announce the sudden death of J. W. GASHWILER, at San Francisco, on the 15th of this month. General GASHWILER was widely known in mining circles, having been early identified with the development of the mines on the Comstock and with the introduction of water into Virginia City. Since then, he has been actively connected with many mining enterprises in California, Nevada, Dakota, and Sonora. He was a man of superior natural abilities and a noble, generous nature, and there are many who will feel that they have ost a genial and valuable friend.

WE seem to be entering upon another cycle of boiler explosions at iron and steel-mills. Only a few days since, a boiler exploded at the works of the Cleveland Iron Company, and to-day comes the news of a worse calamity at the steel-mill of MESSRS. PHILIPS, NIMICK & Co. The technical details in regard to both accidents have not as yet reached us, and it is therefore premature to venture any opinion on the subject. It remains to be seen whether, in both instances, the precautions were disregarded which experience has shown must be observed in such cases. It is not very long since that the experts of the Hartford Steam Boiler Inspection and Insurance Company published a plan for the setting of boilers heated by waste gases in iron and steel-mills. With the exception possibly of saw-mill owners, our iron manufacturers can claim the sorry distinction of being most neglectful in this regard.

MANY of those who are daily testifying before the Senate Committee on Labor and Education in this city are startling their best friends. The temptation to talk carries them off to the discussion of subjects which they do not understand, or to which they have not given due consideration. This week, the Rev. Dr. R. HEBER NEWTON wound up an otherwise clear and moderate testimony by the recommendation that new mineral resources should be reserved for public use, to be worked for the benefit of educational funds. Imagine an army of government prospectors scouring the mountains of the West on salary, men carefully picked from the hangers-on of pot-house politicians of Eastern cities, or the scramble of "superintendents" for appropriations to drive endless tunnels or unfathomable shafts! Dr. NEWTON would be frightened at the annual deficit.

AN idea which, so far as we know, is novel in connection with mine pumping-engines, has been carried out in a lignite mine in Germany. The lignite is obtained by stripping, and the quantity of water accumulating during rainy seasons is enormous. At one of the pumping-shafts, an engine was put in for two sets of pressure-pumps having 2·5-foot plungers and 7·22-foot stroke, the maximum lift being 236·2 feet. The pumps are driven by the engine through the intermediacy of bob, without any gearing. The engine itself is horizontal, with a 27·9-foot fly-wheel weighing 30 tons. It has a 4·59-foot cylinder and 7·22-foot stroke. Its chief peculiarity was, that it was provided with a small special engine, intended to carry the main engine over the dead-center ; when running slowly, the crank of the auxiliary engine being placed at right angles to the main crank. When running without expansion, the engine could be worked at the rate of two revolutions per minute as a minimum, and nine as a maximum, without using the auxiliary engine. When cutting off at three eighths of the stroke, the number of revolutions per minute could not be carried below five. They were, however, brought down to 3½ strokes by the aid of the auxiliary cylinder, which, by the way, had a diameter of 1·60 feet and a stroke of 3·9 feet. The contrivance in question is therefore useful and economical in fuel in those cases where the flow of water is so small that the pumping-engine must be run at the lowest speed attainable.

THE report of the Northern Pacific Railroad Company, just placed before the stockholders, contains some allusions to the traffic from the Montana mining regions secured by the completion of certain sections of the road. It appears that base bullion will form one of the important articles of freight. On one day, July 4th, 511 tons of bullion left Helena, and the Barker District shipped 250 tons from Billings. These quantities may to some extent represent accumulations made in anticipation of lower charges of haulage, still they show that Montana will soon be in a position to come forward as a heavier lead producer, provided the railroad adopts a liberal policy. It is particularly in regard to fuel that the company should lend the mining industries of the territory a helping hand. We presume that for some time to come the output of the Carbonado mines, which is to be increased soon to 1000 tons a day, and of the newly opened collieries at Wilkeson will be chiefly for the company's own use. If the railroad will be content with a fair profit on mining and transportation, it will greatly stimulate the working of smelting ores, copper and lead, and will aid those treating refractory ores of the precious metals. Indirectly, the business which the carriage of supplies and of machinery will bring it will fully compensate for lower returns in fuel. Competition in the base metals is exceedingly severe, and Montana will need all the advantages of cheap transportation to enable it to conquer the place to which it is entitled because of its natural resources.

WHILE no one denies the existence of large quantities of high-grade copper ores in Arizona and New Mexico, we are inclined to believe that the working of lower grade ores will, at no very distant date, attract the attention of managers and metallurgists. There are few mines which can for any great length of time keep up the strain of furnishing ores running from 15 to 25 per cent of metal to even a small smelting-plant which is capable of devouring a great deal of first-class ore. One or two concerns have during the past years shown the welcome signs of working

Digitized by Google

a steadily declining average, a proof that, by greater economy, they are able to be less exacting in their sorting. The accumulation of ores, running from 6 to 10 per cent, on the dumps and in the mines, will, we hope, be an incentive to closer watching of all the details of cost. As yet, smelting raw oxidized ores for a high grade of copper with fuel generally expensive is the rule, and the metallurgical problem is one of the simplest, being reduced to the work of providing the necessary fluxing material. Soon, however, increased cost of development-work, of hoisting and pumping, will counteract waste, and changes in the composition of the ores will force modifications in metallurgical treatment, complicating it. In a longer or shorter time, according to locality, the engineers of that section will have to solve two questions, probably in rapid succession—how to treat their low-grade ores, and how to meet the difficulties of a change in their character. It is urged, with some show of force, that, so far as the low-grade siliceous ores are concerned, especially when suitable fluxing materials can not be had, and when fuel is costly, some of the humid processes of extraction would prove the most economical. Talent of the highest order and mature experience will have to be brought to bear upon the solution of these questions, which ultimately will decide the future of many enterprises.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

Argentiferous and Auriferous Bismuth Ores.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Can you or any of your readers inform me who buys gold and silver ores containing bismuth, and how much they pay for the bismuth? I have about 100 tons carrying 30 ounces of silver, one quarter of an ounce of gold and seven per cent of bismuth. If I can get a price on the bismuth that will pay for mining the ore, larger quantities can be procured. R.

DENVER, COLO., Sept. 11.

NOTES ON THE EXHIBITION AT DENVER.—III.

Special Correspondence of the Engineering and Mining Journal.

GUNNISON COUNTY.

This county is rapidly coming forward to take a front rank among the rich counties of this rich State. Already its principal districts are household words among miners. Colonel Cornwell, the commissioner, kindly supplied me with information respecting the Pitkin District, which he specially represents. The Porcupine group is one of the principal mines in the district, as may be judged from its properties, which consist of eight claims and a placer. There are 1500 feet of tunneling which has disclosed five mineral-bearing veins carrying carbonates and galena in copper-stained rock, assaying from $50 up to $600 in gold and silver. The owners have just started within the last few days to make shipments of ore. One specimen shows a beautiful piece of turquois. The Fairview mine has a 14-foot vein of ore carrying sulphurets and carbonates of lead and copper, bearing silver. The Silver Islet, which also exhibits some rich chlorides and sulphurets with a small quantity of galena, has 1500 feet of development and a vein which runs from 20 to 53 feet wide. The Governor St. John, on Green Mountain, is also represented by specimens of chlorides, etc., showing copper as well as lead. The mine has 300 feet of shafting and levels, and shows a 9-foot vein of ore reported high in silver. The Silent Friend has 300 feet of developments on a 9 to 10-foot vein of the same character of ore as the above-mentioned mines. One block of pure ore shown weighs 2360 pounds. The mine has recently been sold for $800,000. The Mineral Farm is one of the most extraordinary properties represented from this district. As yet, the ore has been found in rich boulders only, one of which is exhibited weighing 3500 pounds. These boulders are often rich in chlorides and sulphurets, and assay from $11 to as much as $500 silver per ton. Efforts are making to find the vein, but as yet without success. The Volunteer mine is well developed, and shows specimens which assay $50 per ton, three fifths gold and two fifths silver. The Midnight has 350 feet of shafting. The Terrible is worked between the limestone and porphyry, and has 300 feet of development. The ore shows bromides of silver with gold, and some of it assays $100 per ton. Two big blocks are shown, containing gray copper ore, and weighing 1000 pounds. The vein is 3½ feet wide. The Quiet Friend, from Quartz Creek, is one of the instances of chance finding so numerous in a country like this. The men were digging out a space for an ore-house, when the diggers suddenly came upon a 3½-foot vein, carrying galena and a copper-stained rock, and assaying $150 silver to the ton. Some rich specimens, assaying $2500 per ton, are shown from Native Silver No. 2. The Way Up mine has 150 feet of development and a 6-foot vein showing galena and lead carbonates in quartzite and calcite.

TIN CUP DISTRICT.

In this department, there are numerous exhibits of good gold and silver ores; but I am unable just now to obtain any reliable information about them.

ROCK CREEK DISTRICT.

We have here an excellent exhibit of ores which are fair ordinary samples, and many of which denote a great future for the district. In this region, are mountains crossed by numerous veins showing mineral at the surface, which as yet are merely prospected. Very few of the specimens exhibited are from mines which have more than 25 feet of development. Mr. R. J. Walter, the courteous commissioner for this district, informed me that, out of about 600 prospected claims, only about five were in more than 100 feet. The following will give some notion of the capabilities of this district. The Eureka lode, which shows some large and rich blocks of solid copper pyrites, assays from 40 to 200 ounces of silver per ton. The Buffalo carries rich steel galena, assaying 75 ounces of silver per ton. The Shakespeare is another mine having steel galena as its staple ore, with a small quantity of copper, assaying 200 ounces of silver per ton. The Homestake has some very fine pieces of ore on exhibition. This lode is the biggest in the country, being 30 feet wide. Some of the ore carries from half an ounce to three ounces of gold, 70 ounces of silver, and from 10 to 30 per cent of copper per ton, much of it carbonate. The King lode lately struck a six-foot vein, carrying 160 ounces of silver per ton. The ore is iron pyrites and galena, according to the specimens shown. The Anna is another very wide lode, containing galena and copper pyrites assaying from 20 to 60 ounces of silver per ton. The Lulu carries that very rich silver ore known technically as antimonial silver, yielding 600 ounces of silver per ton. A contract has been let for several hundred feet of tunneling. The Brockway is a galena-bearing lode, with a small quantity of copper as carbonate on the specimens shown. It will run 40 ounces of silver and 50 per cent of lead to the ton. The Prince of India shows some fine large specimens of copper pyrites and specular iron ore. The Pennsylvania carries what is called "fine galena," and assays 60 ounces of silver and from 40 to 60 per cent of lead per ton. The Grand Republic has specimens of gray copper with iron pyrites, and sulphurets of silver with a little galena, running 300 ounces of silver per ton. The Crown has a galena ore with 75 per cent of silver per ton, and a 16-inch pay-streak. The Whopper has good specimens containing a perfect medley of minerals. The pay-streak is four feet thick. The Milwaukee gives promise of being very rich. The vein is 12 feet thick with a 24 to 36-inch pay-streak, the ore containing ruby silver. The Irene is quartz vein impregnated with brittle silver and some iron pyrites and specular iron. The miners have gone in a good distance, and the yield has been 20 ounces of silver per ton from the surface. The August Flower is an antimonial silver-bearing lode 10 feet wide, of mineral associated with barytes right across. I hardly dare say more, lest I should be thought guilty of attempting to exaggerate; but it seems a pity that such capabilities as are here indicated should lie comparatively dormant for want of courageous capitalists. The district has itself to thank for this. Like so many others, when first its riches were discovered, the owners did not know how to ask enough. Some wanted $200,000 for mere prospects, and capitalists wisely refused to pay any such sum. Now things are very much the other way, and valuable claims can be purchased which are well worth the money asked.

SAGUACHE COUNTY.

The districts represented here are Kerber and Blake, one or two mines only showing from Ford Creek. As a rule, the specimens shown are not at all striking in appearance, and in only a few instances are they very rich. The associated mineral seems to consist chiefly of quartzite, and, as will be seen, the developments are not great. Nevertheless, there are a good number of mines represented. The following list will give some notion of the present status of the principal mines:

Kerber Creek District.

Name.	Depth.	Width of pay-streak.	Value per ton.
Eureka lode	60 feet.	6 feet.	$70
Payson "	100 "	3 "	80
Last Chance "	85 "	3 "	80
Paragon "	200 "	4 "	85
Antoro "	50 "	5 "	100–5000
Boss Mammoth "	84 "	20 inches.	150
Little Elva "	75 "	3 feet.	130–1200
Superior "	100 "	2 "	150– 500
Whale "	100 "	7 "	250

Ford Creek District.

Last Resort lode	105 feet.	30 inches.	385

Blake District.

Wild Cat lode	70 feet.	18 inches.	25–1200
Centralia "	75 "	4 feet.	20– 150
Mountain Lion "	90 "	1 "	65
Anna "	50 "	2 "	340

Several ores show the presence of copper as carbonate. Most of them, however, have the ore as a sulphuret. Whale mine shows a fine large block of ore, as do also several others. Messrs. Norton & Co. show some neat heaps of bituminous coking coal, fire-clay, beautiful crystallized limestone, which seems very pure, and rich brown hematite.

FREMONT COUNTY.

This is the Pennsylvania of Colorado. It contains, in great abundance, coal, oil, and iron ore. I have already had occasion to refer to two of these in speaking of the iron-works at Pueblo. The coal is of a bituminous nature, and makes first-rate coke. The oil, however, is the product which is attracting most attention just now. It is a splendid lubricant as taken from the well, and, as such, though the flow is not so great as in the Eastern oil-regions, it is more valuable, and some say will pay better. The owner of the principal wells, the Land Investment, Coal and Oil Mining Company, shows, in glass vases, from the Peabody well, some specimens of the oil, refined and unrefined. The new well lately struck oil at 960 feet, and is now down about 1100 feet. The company is taking out about 15 barrels per day with the sand-pump. The Peabody well is between 1200 and 1300 feet deep. The fine Brandford freestone is represented by a large carved column. This freestone was employed in building the magnificent court-house at Denver. For ores containing precious metals, this county is not so celebrated as many others; but some fine oxides and carbonates of copper containing silver are shown. One, a red oxide of copper from Green Mountain, contains

Digitized by Google

25 per cent of copper. The company is putting up a smelter to treat it. There is also a fine carbonate of copper ore, a sample of which contained 438 ounces of silver per ton, shown from the mine called Pride of the West. Some bullion is shown from the Royal Gorge smelter, Cañon City, which is shipping about 2½ cars of bullion per day just now. Last year, the output of coal in this county averaged 1036 tons a day, and will exceed that figure this year. The county also produces a very fine mineral paint, and some good plaster of Paris.

CLEAR CREEK COUNTY.

This county, as is well known, is nearly the oldest in this State, being about the first to attract attention to the rich argentiferous galena of the Rockies. Of course, most of the specimens are of this mineral. There are specimens from the Stevens, the first mine of any consequence in the county, and therefore an old reliable. The average run of this ore is from 80 to 100 ounces of silver per ton. The average went up some time ago to about 200 ounces, until it was thought the sample had been manipulated; but it was soon explained by gray copper ore found impregnating the ordinary galena. Some specimens of this shown assay as much as 2000 ounces of silver per ton. The ore runs also from 50 to 60 per cent of lead, being on the average the richest lead ore in the State. The greater part of the mines represented are from the Griffith District, though there are also a good many gold ores from the southern portion of the county. It seems almost impossible to do justice to this splendid exhibit without occupying too much space. It is characterized throughout by the size and rich appearance of its specimens, a feature which distinguishes it from other exhibits. Among the many valuable properties represented may be mentioned the Mascott, on Saxon Mountain, which assays 10 ounces of gold, 90 ounces of silver and 24 per cent of copper per ton. Some fine specimens are shown. The Magnet Sequel mine is leased at a royalty of no less than 70 per cent. The Consolidated Pay Rock is 600 feet deep, and has a mill which works a large quantity of ore each week. The Mint, West Argentine District, which gives great promise, has ore assaying from 150 to 800 ounces of silver per ton. The Meath is also another mine of good promise. It has 1070 feet of development, all in mineral, and only eight fathoms have been stoped as yet. As to the rest, I must give a more concise list:

Griffith District.

	Ounces silver per ton.	Feet deep.
Pelican	400	100
Lebanon Tunnel	686	....
Matilda Fletcher	800-1000	....
Consolidated Hercules & Roe	600	180
Shively	700	550
Baltimore Tunnel	600	....
Griffith	80	50 per cent lead.
Cincinnati	328	....
Bismarck	300	....
Dunkirk	500	410
Dunderberg	225	....
Cashier, 8 ounces gold	40	10 per cent copper.
Mendota	126	110
Diamond Tunnel	100-500	800
City Grove, 2 ounces gold	150-700	6 per cent copper, and some
Vulcan	318	135 lead.
Cliff	600	160

East and West Argentine District.

	Ounces silver per ton.	
Arcadia	100-1000	25-50 per cent lead.
Telephone	200	....
Terrible	528	Some very large blocks of ore.

These are no mere specimen assays, but represent the regular mill-runs. The depth also has nothing to do with the development, which, as is to be expected in such an old district, is very extensive in most cases. In a mine known as the Colorado Central, a large mass of obsidian, containing five ounces of silver per ton, has been found at a depth of 700 feet, some blocks of which are shown. It would be interesting to know what the supporters of the infiltration theory have to say to this.

WYOMING TERRITORY.

Mr. G. E. Bailey, commissioner for this section, has very kindly furnished me with particulars from which I take the following:

First of all, this exhibit is the most tastefully arranged one in the building. Perhaps this is only to be expected, considering that its representative is a lady. In it, the varied resources of the territory are amply displayed. Specimens of its inexhaustible forests, its game, its pastoral products, its coal and iron ores, its minerals, its agates, fossils, marbles, and building materials, its native chemicals and mineral oils, are shown in rich profusion. In one corner, stands a splendid column of sulphate of soda as taken from the deposit. In another, a pyramid of the silver and copper ores worked in this part of the West. In still another corner, stands a pyramid of very rich iron ore, consisting of magnetite from Iron Mountain, Albany County, and hematite from Carbon County. The fossil fish are very fine specimens, some being nearly two feet long. The minerals are many of them very rich, especially in copper.

In the machinery department, the exhibit of Messrs. Lane, Bodley & Co. is worthy of notice. They exhibit a complete full-size smelter, which affords an excellent opportunity to study it in detail. They also show a hoisting-engine in motion. The Webster, Camp & Lane Machinery Company, Akron, O., also exhibits two hoisting-engines. Among the pumping machinery in action, Messrs. Blake show two different types, and there are two exhibits of the Pulsometer Steam Pump Company, New York. A Mack's patent injector is also shown on an ordinary working scale. Messrs. Nichols show a pair of their patent sharp-neck steam stamps on the Ball stamp principle, from which it differs, I believe, in some important details. They are working them successfully at their own place, and I believe at one or two other points now. Messrs. Abendroth & Root have a large stand of their hydraulic pipes on exhibit, and there is also a stand of the Allison patent socket and vanishing thread-pipe with upset ends, and a large assortment of screw-bolts for various purposes.

A. COPELAND.

Sept. 11.

NEW BRITISH STANDARD WIRE GAUGE.

The following has been issued by the Standards Department of the British Board of Trade. The new standard gauge has been duly approved by Order in Council, dated August 23d, 1883, which order will not, however, take compulsory effect until March 1st, 1884:

Descriptive number B. W. G.	Equivalents in parts of an inch.	Descriptive number B. W. G.	Equivalents in parts of an inch.
No.	Inch.	No.	Inch.
7/0	0·500	23	0·0240
6/0	·464	24	·0220
5/0	·432	25	·0200
4/0	·400	26	·0180
3/0	·372	27	·0164
2/0	·348	28	·0148

19	·040	48	·0016
20	·036	49	·0012
21	·032	50	·0010
22	·028		

The following circular has been issued by the same department to the several local authorities under the "Weights and Measures Act, 1878:" "After consulting with the various institutions, local authorities, manufacturers, and others practically interested in the use of wire gauges, the Board of Trade has caused a standard measure for wire, etc., to be made and duly verified, which measure has now been approved by her majesty in council, to be on and after March 1st next, a Board of Trade standard under the act. I am directed, therefore, by this Board to transmit to you a copy of the sizes of this new standard measure, and to ask for the co-operation of your local authority in giving publicity to it in your district, so that by the common adoption in manufacture and trade of a uniform gauge, the annoyance and loss occasioned by the present variety of sizes in use, of which complaint has been made, may no longer arise. I would point out that by the above act it is provided that all measures in use in trade are to agree with the Board of Trade standards, and that it is the duty of the Inspector of Weights and Measures to see that the act in this respect is carried out."

REDUCTION OF ANGLESITE OR SULPHATE OF LEAD TO METALLIC LEAD

Written for the Engineering and Mining Journal by Carl Henrich, M.E., Denver, Colo.

While smelting at the Benson Smelting-Works in Arizona, for lead-silver bullion, I had to use, as a lead ore, ore from the Montezuma mine, which was mainly a sulphate of lead with occasional lumps of galena, and carrying about 60 per cent lead and 11 per cent quartz. The furnace used at the time was a circular water-jacket blast-furnace 10 feet in hight from the tuyeres to the feed-door; 45 inches diameter at the tuyeres; 54 inches diameter at the feed-door; seven 3-inch tuyeres at 10½ inches above the slag-hole. By smelting the above lead ores with dry silver ores and the necessary amount of hematite and limestone, to make a slag between a singulo and a bisilicate, in which the ratio of oxygen of the acid to the oxygen of the bases was as 4:3, besides adding enough iron ore to take all the sulphur of the anglesite and galena and form a matte of the type FeS, the furnace worked very nicely and freely, but of course made a large amount of matte, carrying along considerable silver, and being thereby a source of annoyance, as no roasting appliances were in existence, and it would have been doubtful, besides, whether roasting the matte and working it over would have paid under existing circumstances.

While this state of affairs continued, we received a lot of ore high in silver, carrying about 4 per cent galena, about 8 per cent oxide of iron, and about 25 per cent iron pyrites, the remainder being quartz or silicates. This ore, like all the rest, had to be smelted in its raw state; and smelting in the usual manner, I had to expect making a lot of matte rather high grade (in silver). To avoid this, I tried the following plan:

I thought of the reaction of galena on sulphate of lead in the reverberatory furnace when treating clean galena ores, and also remembered having read that in China anglesite lead ores are reduced to metallic lead by sulphur; and I concluded to try whether a substitution of pyrites for the galena and the sulphur would not work well in the blast-furnace with the additional help of silica, after the formula:

$$x\mathrm{SiO_2}+2\mathrm{FeS_2}+5\mathrm{PbO.SO_3} = x\mathrm{SiO_2}2\mathrm{FeO}+9\mathrm{SO_2}+5\mathrm{Pb},$$

and $\mathrm{PbS}+\mathrm{PbOSO_3} = 2\mathrm{Pb}+2\mathrm{SO_2}$

or that 120 pounds of pyrites would reduce 757·5 pounds of anglesite, and that 119·5 pounds of galena would reduce 151·5 pounds of anglesite, or 1 pound of pyrites would be in its reducing power equal to 5 pounds of galena.

Acting on this calculation, I found that, by putting together in round numbers 350 pounds of the anglesite ore (estimated to contain 15 per cent galena and 75 per cent anglesite) with 100 pounds of the silver ore carrying iron pyrites, both ores ought to reduce each other, and I should get rid of their sulphur in the form of sulphurous acid (SO_2) without producing any matte.

I made the charge accordingly, keeping a lot of scrap cast-iron in reserve, in case the charge should not work as anticipated

The result demonstrated the correctness of my calculation. The fur-

Digitized by Google

nace ran very rapidly and got very hot, so that I had to reduce the ratio of fuel to charge from 1 to 8 to 1 to 9. The resulting slag was very little matte formed, only about 20 pounds in twelve hours, while the furnace smelted from 13 to 14 tons of ore in the same time. Care was taken to save all matte which should form, by letting the slag cool in the pots, and breaking the hardened slag afterward. Only one or two matte cakes of small dimensions were obtained in twelve hours. The pressure of blast was 1⅛ inches mercury. Fuel, coke straight.

I have had no occasion since of verifying this method of reducing anglesite by iron pyrites; but I thought it worth while to call the attention of other metallurgists to this matter, especially in New Mexico, Arizona, and Sonora, where anglesite and pyrites ore occur in great abundance. If any body in these regions has occasion to smelt such ores, I think it may be advantageous to try this method, as the old method of reducing anglesite to sulphide of lead and then precipitating the lead by metallic iron is a very unsatisfactory one, on account of the amount of silver-bearing matte produced, and the almost impossibility of making a slag free from lead.

THE MINING AND METALLURGY OF ZINC IN THE UNITED STATES.*

By F. L. Clerc.

(*Concluded from page* 169.)

CENTRAL ZINC-WORKS.

Works in Illinois.—Of the works at La Salle and Peru, Illinois, only a general description can be given. They produce at present considerably more than half the metal made in this country. The works at La Salle were started about the year 1860; they belong to the Mathiessen & Hegeler Zinc Company, and have a capacity of from 28 to 30 tons of metal a day. The most striking feature about these works is the patented furnace employed. This furnace is in the neighborhood of 100 feet long, and contains about 800 retorts, of the same general size and shape as in the old Belgian furnace, and set into the furnaces in the same general way, but only five rows high. The furnace is fired by gas produced by a blast in a producer outside of the furnace. The producer is set close to one end of the furnace, but on a lower level; is of square cross-section, and has an air-tight iron ash-pit raised from the ground, into which air is forced by a large iron fan. The front of the ash-pit is closed by planed iron doors, which are raised by counterpoises when the fires are cleaned and held closely in place by suitable clamps when the air is admitted. The producer is covered by iron doors, which open half-way across the top when the producer is being charged. The coal is mined under the works, and dumped directly into the producer from the mine cars. The gases are led hot into the end of the furnace, and are gradually burned as sufficient air is admitted. The air for combustion is brought from the opposite end of the furnace, through a flue running over the center of the furnace arch; from this flue, lateral branches are taken off, at right angles, to both fronts of the furnace, and carried down to the floor level at such intervals as to admit four retorts in a horizontal row between successive air-flues. All these flues are external to the furnace, and the air is admitted into the combustion-chamber through perforated fire-clay tubes, corresponding in size, position, and arrangement with the charged retorts. Dampers to regulate the supply of air are introduced at intervals in the flues; when once adjusted, they do not require to be often changed. Contrary to what might be expected, the heat is tolerably uniform throughout the length of the furnace, but slightly less at the end remote from the producer, where the charge is modified to suit these conditions. The first furnace built was provided with stoves to heat the air by burning the gases escaping from the furnace. These stoves are a combination of iron and fire-clay pipes, through which the air passes, while the gases burn on the outside, and are about as large as are required for a 50-ton iron blast-furnace. Later furnaces have not these stoves, but room is left for them in the furnace buildings. It would seem, therefore, that there is still a question as to their economy. Probably the same may be said of the whole furnace.

Except for the use of suspended retorts, several rows high, and some peculiarities in the producer, there is little essential difference between this furnace and the step-grate furnaces with blast, employed in Silesia. It certainly has many of the advantages due to the use of gas-firing, and special advantages due to mechanical devices for working it; but, on the other hand, without the effective heating of the blast, and the utilization of the escaping heat of the furnace, it can not be considered an altogether successful contrivance, and the construction involves points which seem to render maintenance and repairs very expensive. Among the inventions to facilitate working may be mentioned: cars for cleaning and charging the retorts, cars with swinging ladles for drawing the metal, derrick-cars for taking out and replacing the retorts, all provided with suitable screens for protecting the workmen from the heat, and all moving on a track laid close to the furnace. Also, two story bins for the charge, to follow close behind the charging-car; a car carrying moulds for casting the metal; and trays for the collection of the blue powder.

Of the roasting-kilns, there are many varieties. In most of them, the ore gradually falls from the top of the kiln upon a succession of inclined shelves, meeting the hot air or furnace gas passing up through the kiln. The latest mechanical kiln has more points of novelty, and some good features. It is worked in connection with sulphuric acid chambers. This kiln is something like 75 feet long, and has five or six flat hearths, one above the other, with lateral cast-iron doors, not ordinarily used, and working doors at the ends. The ore is charged on the several hearths at one end of the furnace, and is carried to the opposite end by mechanical means. The handle of a rake is rapidly projected through one of the hearths and out of the working-door at the opposite end of the furnace, where the head of the rake is quickly attached to it; the rake is then drawn back through the furnace by the reversal of the same machinery which projected the handle. When it reaches the discharging end, the rake-head is detached, and is received on a car with decks corresponding to the hearths of the furnace, and carried back to the far end by the car moving around the furnace. There are as many handles and rake-heads as there are hearths. The sliding doors are raised and lowered so as to admit as little false air into the kiln as possible. The form and dimensions of the rake-teeth determine the amount of ore discharged by each draw through the furnace. The whole operation is quickly performed, and the doors are open only a few seconds at a time. Two sets of sulphuric acid chambers, each of a capacity of about 240,000 cubic feet, with all modern improvements, have recently been added to the works.

In the large rolling-mill of the company, there are six pairs of rolls; and the same desire is shown here as elsewhere to supplement manual labor by machinery. With rapidly moving rolls, and three eight-hour shifts a day, the output is pushed to the utmost. The capacity of the mill is over 100,000 pounds of sheets in twenty-four hours. To keep these works running steadily, the company, which mines no ore, is obliged to always carry a large stock on hand, which often must represent several hundred thousand dollars of capital. The system of sampling and mixing the ore is good, as is also the preparation of the retort mixture of clay. The retorts are shaped by machinery, the clay being forced by a propeller-like screw through a die-plate and around a mandrel; a man below receives it in an adjustable mold, into which he allows it to be forced with all the pressure it will bear without bending; when it reaches the bottom, he stops the machinery, cuts off the retort, and turns it over to another man, who stamps in the bottom and smooths up the retort. This process is said to give as good retorts as can be made by hand; but certainly not so good as those made in Belgium by hydraulic pressure in molds. The condensers are stamped out by a drop-plunger of the required internal shape. Besides four large furnaces, this company has a number of common Belgian furnaces, which have, however, been altered from direct firing to gas-firing, by building a semi-detached fireplace against one side. In other respects, also, crude and obsolete constructions may be found working side by side with the latest perfected inventions; and it can scarcely be doubted that the preponderating influence of these works on the zinc industries of this country is due less to their economy in working, or the excellence of any of their furnaces, than to the peculiar advantages they have enjoyed in the past in the matter of cheap ores, their abundant capital made in the business, their extensive knowledge of the metal trade, and the monopoly they enjoyed for many years of the sheet-zinc market, during which time the price of sheets ruled about two cents a pound higher than the price of metal.

The Illinois Zinc Company, whose works are at Peru, across the river from La Salle, have the next largest works in the country, with a capacity of from 18 to 20 tons of metal a day. There are three gas-furnaces in use, in addition to eight ordinary furnaces. The gas-furnaces were built under license from the owners of Siemens's patents in this country, and present several improvements over the earlier designs of Dr. Siemens of several years ago. The bottom of the furnace chamber is a solid floor of brick, and the air and gas-ports are raised above it, and come through the back wall of the furnace under the lower row of retorts. Another improvement is the placing of an auxiliary gas-box with a simple two-way flap-valve over the ordinary reversing butterfly valves, by means of which either set of regenerative chambers may be run on gas or air. By an occasional reversal, deposits of soot in the gas-chambers may be burned out, and to some extent deposits of oxide may be removed; but as the only escape for the zinc when it gets from the retorts into the combustion-chamber is through the regenerators and valves into the chimney, the principal effect on the oxide must be to drive it from one place to another in the furnace. It is said, however, that, with the recent improvements, the trouble from oxide is not serious, and that the furnace never has to be shut down on purpose to clean the regenerators, and will run two years without needing repairs. The furnace is about 60 feet long, and contains about 144 retorts on a side, three rows high, 48 retorts in a row. The four regenerators extend the whole length of the furnace, are about 28 inches wide, and contain about 30,000 bricks. In these works, the furnace is charged only once in twenty-four hours, and the retorts in the bottom row are considerably the largest, and have an elliptical shape. The charge is 17,000 pounds of calcined ore for an ore yielding 8000 pounds.

The gas-producers are of the ordinary type, and the management of the valves is the same as with any Siemens furnace. A rolling-mill with three sets of rolls, driven by a large engine with great reserve of power, has been started within a year. The rolls, housings, and general equipment of the mill are of first-rate design and construction. For many reasons, a separate engine for "breaking down" the ingots would seem to be preferable.

Works near St. Louis.—There is another group of zinc-works in the neighborhood of St. Louis, using Illinois coal, and drawing their supply of ore from the southeastern and southwestern lead regions of Missouri. Of these works, only two, the one at Collinsville, Illinois, and the Glendale Works at Carondelet, have run at all steadily for the past year or two. The Missouri Zinc-Works and the Carondelet Zinc-Works have stood idle for some time. Of these four works collectively, it may be said that they have passed through many vicissitudes; they have been repeatedly started up under different managements, and have always been among the first in the country to shut down when ores are high or metal low. There is nothing noteworthy in their general construction. Until quite recently, they have been dependent upon a single road for their ore supplies, and the works on the Missouri side of the river have had to pay extravagant prices for fuel. Whether these two causes alone, or joined with the lack of sufficient capital, are enough to account for their irregular record, and to offset their natural advantages of location, it might be a matter of some difficulty to determine. Large retorts, large furnaces (for direct firing), and twenty-four-hour charges, seem to have been the prevailing practice. It may be mentioned, for the benefit of any one thinking of repeating the experiment, that there are two nearly new blocks of two furnaces, each furnace containing 198 retorts, nine retorts high, with 22 retorts in a row, to be seen at the works of the Missouri Zinc Company.

WESTERN ZINC-WORKS.

On the bituminous coal belt extending from the Indian Territory through Eastern Kansas into Northern Missouri and Iowa and on lines of railroad penetrating into the lead region of Southwest Missouri, is located another group of works. The oldest of these is at Weir City, Cherokee

* From advance-sheets of *The Mineral Resources of the United States*, published by the United States Geological Survey, Department of Interior, Statistics. Albert Williams, Jr., Chief of Department.

County, Kansas, about twenty-five miles from Joplin on a branch of the Kansas City, Fort Scott & Gulf Railroad. The first furnaces were built in 1873, before railroad communication was established. Ore and coal were then exceedingly cheap, but the former had to be hauled from twenty-five to thirty-five miles in wagons, and came mainly from Jasper and Dade counties. The works were built on a stripped coal-bank, in the open prairie, and four miles from any town. Skilled labor was hard to get and high-priced, and the class of men first employed was very turbulent and unsatisfactory. The works have undergone many changes, and it is only recently, under the present management, that they have assumed importance as producers. Ten miles from here, on the same coal-field, at a point which has since become the town of Pittsburg, R. & S. H. Lanyon started two furnaces in 1878; the number of furnaces has since been increased to eight, each furnace containing 98 retorts. In 1880, the partnership was dissolved, and Mr. S. H. Lanyon began the erection of new works alongside of the old one; he has now four furnaces similar to the foregoing. In 1882, W. & J. Lanyon put up two similar furnaces in the same immediate neighborhood, which are now running. The Granby Mining and Smelting Company in the same year began the erection of works, using the Siemens gas-firing furnace, at this place, and is now engaged in smelting. The town of Pittsburg is twenty-eight miles from Joplin, and on branches of both the St. Louis & San Francisco and the Kansas City, Fort Scott & Gulf railroads; it has now a population of about 3000, and is the principal coal shipping station on the former railroad. The West Joplin Lead and Zinc Company has, within a year, built zinc-works at Joplin, which are now running with a capacity of six furnaces containing 644 retorts. Within the same period, the Southwestern Lead and Zinc Company has erected at Rich Hill, Bates County, Missouri, on the same coal-belt, about 80 miles from Joplin, with which it has connection by two railroads, a Siemens gas-furnace containing 288 retorts, which has been running some six months, and has just completed a block of direct-firing furnaces.

Economic Conditions of Zinc Metallurgy.—This unusual activity in furnace building is likely to produce considerable uncertainty in the zinc market for some time to come. All of these works possess advantages of cheap coal (about 50 cents a ton for slack and from $1 to $1.50 a ton for the run of the mine) and low freights on ore, from $1 to $1.50 a ton according to the shipping point; living is cheap for their men, and the country around them is rapidly filling up with new-comers; foundries, boiler and machine-shops at Joplin, Rich Hill, and Fort Scott supply castings at from 3 to 3½ cents a pound and machine work at reasonable rates; labor is abundant and wages moderate. There is little to be noted in the form of the direct-firing furnaces in use in this district. In the Lanyon furnaces, the four lower rows of retorts are charged twice in twenty-four hours; the retorts of the upper rows, which are charged with blue powder, are both longer and wider than the lower ones; the back wall of the furnace being made thinner at the top than at the bottom, to admit of this arrangement, which commends itself to reason, as the blue powder is easier to reduce than ore and the charge is longer in the furnace. The furnaces are built with the ash-pits above the ground and on a level with the rest of the works; a sloping bank of earth or cinder leads up to the furnace-floor. The buildings are all of the simplest and lightest construction possible, scarcely more than sheds, and are huddled together, with little regard to their mutual relations. In such works, at present, it seems that metal can be made as cheaply as in any works in the country. Their first cost is very inconsiderable; the flat ledges of Coal Measure sandstone in the neighborhood furnish cheap and serviceable material for building foundations and ash-pits; the peculiar mining systems of the district make small or second-hand engines, boilers, and crushing machinery comparatively inexpensive; cheap fuel renders economy in this direction unimportant; and cheap living causes ordinary yard labor to be easily obtainable at wages as low as prevail anywhere in the country. When the potteries are in operation, all refuse refractory material can be cheaply worked up into some sort of building material. The furnace walls are laid with the ordinary clay underlying the coal. The coke for the charge is jigged out of the cinders from the ash-pits. The general mildness of the winters enables most of the work to be done in the open air. The potteries are heated by stoves or by fires built in worn-out boilers. If the buildings do not blow up or burn down, as occasionally happens, the interest on capital is very insignificant. The works are usually owned by partners who do the work of salaried employés, buying the ore and selling the product, superintending the smelting operations, and occasionally taking a hand as mechanics, who consider as a profit what would only be the interest on their money and their wages at some other occupation. The furnaces, roughly constructed of inferior material, will not long sustain the heat required to exhaust the zinc from the cinder, and it is the accepted opinion that there is no economy in "butchering" the furnace for the sake of a small additional percentage of metal; it is preferred to increase the production of the furnace and reduce the smelting expenses of labor and fuel by increasing the charge of ore—in other words, to butcher the ore and save the furnace. Analyses of ores and cinders are entirely neglected.

But the most secure advantage these works have over those at a distance comes directly from the manner of buying the ore. It has been seen that ores are not sold on their contents of metal, and that the miners are absolutely ignorant of their value; ores differing 5 or 6 per cent are often held at the same price. A personal knowledge of the ores of particular diggings, and their behavior and yield in the furnace, often enables the smelters, by a slight advance in price, to pick up desirable lots of ore and at the same time raise the price of all the ore held in the neighborhood. The smelters at a distance, buying in very much larger quantities, through agents who are ignorant of other branches of the business, are placed at an evident disadvantage. This system of personal supervision of all branches of the business by the owners of works is clearly applicable only to very small works; while labor-saving machinery and facilities for handling the ore can only attain the maximum economy when large amounts of material are to be handled—consequently, when the works are large, and the machinery is constantly kept employed. On the other hand, under these favorable circumstances, in every prosperous owner of a mining lot and in every enterprising furnace brigadier are to be seen the possible proprietors of new smelting-works. It is from lack of sufficient capital and knowledge of the commercial part of the business to market their product advantageously that the weakness of such companies mainly arises. The accumulation of a few months' metal is sufficient to tie up all their capital and exhaust their available credit Sales are made through commission men, with orders to sell the metal for what it will bring. Large consumers, knowing the condition of affairs, are careful to get the lowest bids before making purchases. Large metal houses, who might otherwise dispose of the whole product, are not disposed to have much to do with it; for no price above actual cost price is safe to buy the metal at in order to sell it again. Occasional good sales, or cheap lots of ore, give uncertain profits; and a slight rise in the price of metal is sufficient to "fire in" new furnaces. Under such circumstances, no real advances in the metallurgy of zinc are to be expected.

Two companies controlling large bodies of mineral land—the Southwestern Lead and Zinc Company and the Granby Mining and Smelting Company—have been driven to undertake the smelting, in part, at least, of their own ores, in the hope of obtaining a certain sale for their ore product, which will enable them to pursue some definite policy in the management of their mines. The undertaking is not without its difficulties in the present state of the zinc industries. The strength of their position lies in their ability to supply their works with ore, without the risk of carrying a large stock on hand, and at the same time to develop their mines and increase the amount of their royalties and their profits from lead smelting.

Comparative Merits of Furnaces.—The advantages of a gas over a direct-firing furnace are briefly these:

1. A saving in fuel, which is plainly proportional to the extent to which the heating power of the gases escaping from the furnace is utilized. For heating the air or gaseous fuel, nothing is likely to supersede the Siemens regenerators.

2. A saving in wages, due to the simplification of the work and the less amount of labor required. The furnace can be built larger, without being above the reach of a man on the floor; and a man on a table exposed to the full heat of the furnace, with a man on the floor to wait on him, is no longer required. One set of men can fire for several furnaces at the same time.

3. A saving of metal and retorts; for the control of the heat is so perfect that the temperature of the furnace can be kept at the point needed to fully reduce the charge without running the risk of burning out the furnace or cutting down the retorts. But the full importance of such advantages, like the economy of building well and putting in the best devised labor-saving machinery, will only be realized when the cost of smelting at the different works affects their profits more directly than do their facilities for getting cheap ore and disposing of their products to advantage.

General Conclusions.—From the foregoing rapid survey of an extensive field, these conclusions may safely be drawn:

1. That we are rapidly exhausting the richest portions of our known ore-deposits.

2. That our methods of mining are reacting unfavorably on our furnace practice.

3. That the future of our zinc industries is uncertain and beset with many dangers.

When it is borne in mind that our production of spelter is less than one seventh that of Europe, while the average yield of the ores we treat is nearly twice as great as the average yield of the whole of Europe and nearly three times as great as that of the ore treated in Silesia, whose metal rules the price of spelter in the world's market, it will be evident that many changes must take place before it can be said that we are making the most of our opportunities. It is not within the scope of this article to discuss the policy of the smelters toward the ore-producers or toward each other, or the uses to which zinc is put, which determine the amount consumed or the price that can be paid for it; but it may be noted that, from the rapid extension of the use of galvanized iron and of telephone and telegraph lines and other applications of electricity, the market for zinc is rapidly extending, and that, except for purposes of roofing (which are almost unknown in this country, but absorb the bulk of the sheet-zinc rolled in Europe, where the zinc comes into competition with tinned iron), there are few uses for zinc in which the consumption would be materially lessened by a considerable increase in its price; and that, from the difficulties to be overcome in mining and smelting, it seems probable that, relatively to other metals, zinc is at present undervalued. It is not to be desired that any smelting company, so long as it can buy ores profitably, should engage in mining, or should pay any more than it is obliged to for ore, or buy any quality of ore but what it finds most profitable. Nor is it to be expected that any mining company should change from a system which it finds sufficiently profitable, or employ its capital in any way but the one which yields the greatest profit. But it is very desirable that some record should be kept of present mining operations, and such knowledge gained of the mineral regions as will justify the employment of greater capital and render possible the introduction of better methods of mining and utilizing the ore. The geological surveys of Wisconsin and Missouri have done good work; but the fields covered by them are very extensive, and much more yet remains to be done. The huckstering of the ore and the metal, however profitable it may be to the persons engaged in it, is unfavorable to the mines and to the development of manufacturing industries. The fluctuations in price attendant on it are alike injurious to the producer and the consumer—more so, in fact, than would be a low price to the producer and a high one to the consumer. The remedy can only come gradually and with time.

THE Bradford mines are to be saved from the dangers of flooding by the construction of a seven-mile ditch, thirty feet wide, from the coal-fields to the Kankakee River. The vast mining operations which for years have been carried out at Joliet have caused a general depression in the land, which was naturally flat and level, so that, whenever it rained, the waters were kept as in an immense basin, forming a great lake. The ditch will carry it off and prevent the annual damage done to the mines.

THE SHELF DRY-KILN.*

By C. A. Stetefeldt, New York City.

In the dry-crushing of ores, either by stamps, rolls, or other machinery, it is essential that the material should be free from moisture. Hence a contrivance which effects this with economy, and is of durable and compact construction, is a great desideratum. It is claimed for the below-described shelf dry-kiln that it possesses these qualifications in a high degree.

The construction of the shelf dry-kiln† is based on the Hasenclever principle. That is to say, a number of inclined shelves are arranged zig-zag above each other in a vertical shaft, having openings or slits where they meet, on which the ore rests in a stratum, the thickness of which is governed by the width of the slits and the inclination of the shelves. If a portion of the charge is removed at the end of the bottom shelf, a sliding motion of the ore takes place on all shelves above, and the top shelf is replenished from a hopper set over it. It will be seen that the shaft is divided by the shelves into a number of triangular prismatic spaces. Through these, the hot gases from a fire-place are made to circulate, each space communicating with the next one by a flue arranged in the side-wall of the shaft. These flues being located on alternate sides of the shaft, a continuous passage is formed through the whole structure.

After thus stating the principle of construction, its details will be easily understood by reference to the drawings, Fig. 1 to Fig. 5. The drawings, Fig. 1 to Fig. 4, represent two kilns united into one structure. The cast-iron shelves *a* are 2 feet 4 inches wide and 5 feet long, with sides and a back 4 inches high, and are cast a full half-inch thick. How they rest on the brackets *d*, and interlock each other, is shown in Fig. 5. Three such shelves, with an inclination of 38 degrees, are placed in one row in a brick shaft 7 feet ½ inch wide and 4 feet deep. The ore-hoppers *g* rest on iron beams *f*. At the end of the bottom shelves are the discharge-doors *b*, with chutes projecting beyond the front wall. A swinging apron *c* keeps the ore in place. By dropping it, a car below the chute is filled with dry ore. A number of extra-large pieces of ore may cause a stoppage in the slits; for such an emergency, the openings *e* are provided, through which a poker can be inserted. The fire-place, with air-channels *h*, is located near the base of the kiln, but its hot gases enter below the top row of shelves, and move downward, finally escaping through the flue *k*, which is connected with a chimney. Such an arrangement is made for very good reasons. If the fire entered below the bottom row of shelves, which are filled with dry and hot ore, a careless laborer might overheat and warp them by too heavy firing. As it is, the greatest heat strikes those shelves which are filled with cold and moist ore, and overheating can hardly occur. With a downward draught, the temperature of the kiln is very uniform, and the evaporated moisture can not condense again by coming in contact with cold and wet ore. The opening *i* in the front wall is closed either by a brick wall or a sheet-iron door. The hight of the kiln from the discharge-floor to the top of the hoppers *g* is 21 feet, more or less, depending somewhat on the hight of the car to be used for transporting the dry ore to the crushing machinery. The brick-work is heavily anchored with beams, rails, bolts, and buck-straps, which are not shown in the drawings.

In constructing the kiln, none of the shelves is put in position until the shaft is finished to the level of the beams *f*, and the brick-work is fully anchored. In order to avoid difficulties in placing the shelves, it is best first to fit them, set after set, into an exact wooden model of the shaft (2 feet 4 inches wide), which is put up on the fireman's floor, not in a vertical but in a horizontal position.

Since a good draught is essential for drying the ore quickly, the chimney should not rise less than 30 feet above the top of the kiln. For one double kiln, a draught area of 3 square feet is required.

In case the kiln is used for drying salt, some remarks about its operation may not be out of place. The wet salt on the top row of shelves first bakes into a solid cake. By increasing the fire, decrepitation of the salt-crystals commences, and the whole mass is shaken loose, with exception of a crust on the top. This is broken up by means of a light poker with chisel end. If the fire is kept right, no rebaking of the salt takes place on the second row of shelves, but violent decrepitation continues here and lower down. The constant impact of the decrepitating salt-crystals has, in the long run, a destructive effect on the walls of the kiln, if they are built of ordinary soft brick. Hence it is necessary to line the salt-kiln with very hard-burnt common brick or with fire-brick. The drying of the salt is very perfect. Two double kilns for ore and one single kiln for salt have been in operation at the Lexington Mill, Butte City, Montana Territory, since September 1st, 1882. Mr. A. Wartenweiler, a member of the Institute, gives the following statistics as to the capacity and consumption of fuel and labor of this plant. The two double kilns put through 54 tons of ore, with about 4 per cent of moisture, and consume 2 cords of wood in twenty-four hours. In calculating the consumption of wood for several months, it is found that 0·039 cords of wood are used for drying 1 ton of ore. One single kiln puts through 8 tons of salt (dry weight), with about 6 per cent of moisture, and consumes 1 cord of wood in twenty-four hours. In calculating the consumption of wood, as above, it is found that 0·11 cords of wood are used for drying 1 ton of salt. The capacity of the salt-kiln is somewhat overtaxed, and a heavy fire has to be kept. In consequence, the upper shelves, next to the fire, warp after some time.

One man in each shift attends to the fire-places and the salt-kiln, and one man in each shift discharges the dry ore and salt, and transports it to the self-feeders of the batteries. All shifts in the mill are eight-hour shifts.

The weight of the iron plant for one double kiln, consisting of castings, wrought-iron work, beams, rails, buck-straps, and bolts, is about 25,000 pounds. The quantity of brick required is 30,000. It may be stated that every thing is constructed with a view to durability.

Compared with the revolving or cylindrical dry-kiln, the following advantages are claimed for the shelf dry-kiln:

1st. Greater compactness of construction and greater durability.

2d. Greater economy in fuel, since very little heat is lost by radiation, and the heat is better utilized by traveling through a much longer space.

3d. No power is required in its operation.

4th. It produces no dust, hence no necessity of erecting dust-chambers, and no loss in precious metals from this source.

* A paper read at the Roanoke Meeting of the American Institute of Mining Engineers, June, 1883.

† Covered by United States patent, granted to C. A. Stetefeldt, March 1st, 1881.

GOLD MILLING IN AUSTRALIA.

There is nothing more calculated, says the London *Mining Journal*, to insure energy and lead to careful manipulation on the part of mine managers than the publication of details as to the practice adopted and results obtained in various mines and mining districts. When one finds that he is obtaining better results than others in the same profession, he is naturally inclined to use his utmost efforts to maintain his pre-eminence; and should he be unfortunate enough to learn that his work displays carelessness and incompetency, he may be induced to attempt to improve. Such being the case, it is scarcely possible to attach too much value to the subjoined particulars with reference to Australian practice which have been collected by the mining surveyors and registrars relating to the weight and cost of the stamps made use of in some of the principal gold mines in the several mining districts, and which supply additional information connected with the process of crushing quartz during last year:

In the Ballarat Mining District, the stamps vary in weight from 3 to 9 cwts., and the cost is from 12s. to £1 per cwt. The fall of the stamp ranges from 7 to 14 inches. The number of strokes made per minute is from 50 to 83. The quantity of quartz crushed per head per diem of twenty-four hours varies from 1 ton 4 cwts. to 3 tons 17 cwts. The number of holes per square inch in the gratings used is from 75 to 256. The horse-power required to work each stamp is from 7-10ths to 1¼. The quantity of water used per stamp in crushing varies from 24 gallons to 770 gallons per hour. The quantity of mercury used in the riffles per stamp is from 2 pounds to 32 pounds. The quantity of mercury lost per per stamp per week is from a quarter of an ounce to 12 ounces.

In the Beechwort Mining District, the stamps vary in weight from 3 cwts. 3 qrs. to 13 cwts., and the cost is from 16s. to £3 per cwt. The fall of the stamp ranges from 5 to 20 inches. The number of strokes made per minute is from 40 to 90. The quantity of quartz crushed per head per diem of twenty-four hours varies from 1 ton to 2 tons 15 cwts. The number of holes per square inch in the gratings is from 80 to 260. The horse-power required to work each stamp is from ¾ to 2½. The quantity of water used per stamp in crushing varies from 40 gallons to 1200 gallons per hour. The quantity of mercury used in the riffles per stamp is from 9 to 56 pounds. The quantity of mercury lost per stamp per week is from half an ounce to 4 ounces.

In the Sandhurst Mining District, the stamps vary in weight from 6 cwts. to 8 cwts., and the cost is from 14s. to £1 10s. per cwt. The fall of the stamp ranges from 6 to 12 inches. The number of strokes made per minute is from 60 to 65. The quantity of quartz crushed per head per diem of twenty-four hours varies from 1 to 2 tons 10 cwts. The number of holes per square inch in the gratings used is from 80 to 200. The horse-power required to work each stamp is one. The quantity of water used per stamp in crushing is 255 gallons per hour. The quantity of mercury used in the riffles per stamp is from 6 to 36 pounds. The quantity of mercury lost per stamp per week is one ounce.

In the Maryborough Mining District, the stamps vary in weight from 5 cwts. to 8 cwts., and the cost is from 14s. to £1 12s. per cwt. The fall of the stamp ranges from 7½ to 12 inches. The number of strokes made per minute is from 60 to 76. The quantity of quartz crushed per head per diem of twenty-four hours varies from 1 ton 8 cwts. to 2 tons 14 cwts. The number of holes per square inch in the gratings used is from 81 to 290. The horse-power required to work each stamp is from 1 to 1½. The quantity of water used per stamp in crushing varies from 320 to 900 gallons per hour. The quantity of mercury used in the riffles per stamp is from 2 to 20 pounds. The quantity of mercury lost per stamp per week varies from 1 to 12 ounces.

In the Castlemaine Mining District, the stamps vary in weight from 6 cwts. to 8 cwts. 1 qr., and the cost is from 14s. to £1 12s. per cwt. The fall of the stamp ranges from 7 to 12 inches. The number of strokes made per minute is from 60 to 75. The quantity of quartz crushed per head per diem of twenty-four hours varies from 10 cwts. to 2 tons. The number of holes per square inch in the gratings used is from 81 to 200. The horse-power required to work each stamp is from ½ to 1. The quantity of water used per stamp in crushing varies from 240 to 666 gallons per hour. The quantity of mercury used in the riffles per stamp is from 4 to 20 pounds. The quantity of mercury lost per stamp per week varies from half an ounce to 18 ounces.

In the Ararat Mining District, the stamps vary in weight from 6 cwts. to 9 cwts., and the cost is from £1 2s. to £1 12s. per cwt. The fall of the stamp ranges from 6 to 10 inches. The number of strokes made per minute is from 70 to 75. The quantity of quartz crushed per head per diem of twenty-four hours varies from 1 ton 1 cwt. to 2 tons 10 cwts. The number of holes per square inch in the gratings used is from 120 to 342. The horse-power required to work each stamp is from 0·5 to 1·25. The quantity of water used per stamp in crushing varies from 528 to 800 gallons per hour. The quantity of mercury used in the riffles per stamp is from 20 to 75 pounds. The quantity of mercury lost per stamp per week is from 6 to 29 ounces.

In the Gippsland Mining District, the stamps vary in weight from 1 cwt. to 8 cwts., and the cost is from £1 2s. 6d. to £5 per cwt. The fall of the stamp ranges from 6 to 40 inches. The number of strokes made per minute is from 18 to 80. The quantity of quartz crushed per head per diem of twenty-four hours varies from 6 cwt. to 2 tons 16 cwts. The number of holes per square inch in the gratings is from 60 to 240. The horse-power required to work each stamp is from 1 to 2. The quantity of water used per stamp in crushing varies from 60 to 480 gallons per hour. The quantity of mercury used in the riffles per stamp is from 5 to 38 pounds. The quantity of mercury lost per stamp per week varies from half an ounce to 10 ounces.

THE CHEMICAL TRADE OF THE NORTH OF ENGLAND.

There are few industries, says the *Times*, that show in the past few years such marked changes as that of chemical manufacture. This is because the trade has been for some time in a state of transition. An old process is in course of being slowly supplanted by a newer one; and what in one process has been a by-product seems likely to change places with that which was the chief object of the carrying out of the process. Thus, there has been a fluctuation in the demand, and a response in prices. The chief articles produced by the chemical manufacturers of the north of England are soda ash, soda crystals, and bleaching-powder. Taking soda crystals first, at the beginning of each quarter of the year 1881 the prices were £2 16s., £2 14s. 9d., £3, and £2 16s. 9d., and at the same period of the past year the prices did not vary much above 2s. from these prices. But in the present year, the prices have varied in a considerable degree. Between the beginning and middle of the year, soda crystals rose from £2 12s. to £3 1s., and bleaching-powder from £4 to £5 10s. The former article has scarcely maintained its price, but the latter has risen still further, and is now £7 15s., so that in seven months the price has been nearly doubled. The cause of the change is largely the increased production of soda ash by the newer ammonia process, and the decay in the manufacture of that form of soda by the older Leblanc process. This decay has continued until, instead of twelve or fourteen alkali manufacturers on the north bank of the river Tyne, there is not one now. Bleaching-powder, which used to be merely a by-product—the hydrochloric acid being considered in some instances so worthless that it was wasted—has advanced in price so rapidly that the manufacturers are almost of opinion that it will be the chief product by the Leblanc process, and soda crystals the by-product, made not because of the profit, but made in the process of the manufacture of the more profitable article. Under the agreement of the makers of the bleaching-powder, the extent of the production is regulated till the end of next year; and as that article is only made by the old process, and as the latter is not extending, there is no probability of a large increase in the extent of production. The demand for paper making and for allied uses, as well as for sanitary purposes, is growing, and thus there may be a return to higher prices. These changes in price, and in the comparative cost of production, have materially altered the course and prospects of the chemical trade of the county of Durham; for by the dying out of the trade on the north bank of the Tyne the manufacture of chemicals in large quantities in the north is now nearly confined to that county. The utilization of the salt deposits of South Durham will before long introduce into South Durham the production of soda by the ammonia process.

GRAPHITE.*

By John A. Walker.

Occurrences.—As a mineral, graphite is widely distributed in the United States; as an ore, it is found in but few places in sufficient quantities and purity to be profitably worked. It is found in the older rocks of the Appalachian chain from Alabama to Canada. Several discoveries of it have been reported from Michigan. Mr. F. F. Chisolm reports its occurrence in "great purity in five different localities in Albany County, Wyoming Territory, in veins from 18 inches to five feet thick. In Colorado, it is found in different parts of the State. At Pitkin, in Gunnison County, it occurs in beds two feet thick, but very impure. In New Mexico, pure graphite is found in small quantities in the Coal Measures, where it is probably the result of metamorphism. Graphite occurs sparingly in the Black Hills of Dakota." It has been mined at the Sonora mine, Tuolumne County, California.

Of the Eastern deposits, those of Pennsylvania, New Jersey, New York, and Canada are of the crystalline or foliated variety, are the best known, and are the only ones which are at present worked. The deposits occurring in Alabama, North Carolina, and Virginia are of the amorphous variety. These are of such a nature that purification is economically impossible. They can be used only in the crude state and for but few purposes. The Western deposits are still undeveloped.

Origin and Characteristics.—Graphite is now generally conceded to be of organic origin—the result of the metamorphism of some of the products of destructive distillation of vegetable tissue. It occurs in veins, beds, and disseminated through strata (graphitic schists). The veins occur principally in New York, Canada, and the far West. They are true fissures in gneissoid rock. The vein graphite is usually associated with calcite and quartz. Pyroxene, mica, and apatite are sometimes found with it. Crystals of calcite are found which, on being split, show scales of foliated graphite along the planes of cleavage. Graphitic schists are found in the same regions as the veins, and also in New Jersey and Pennsylvania. These are metamorphosed sandstones with foliated graphite very evenly disseminated throughout in small flakes. The graphite found in beds is amorphous, and occurs principally in the South. It is in a sedimentary formation, is quite impure, and on account of its fineness can not be successfully purified. Geologically, graphite occurs from the Coal Measures back to the eldest rocks. (See article by Professor Frazer, Transactions American Institute of Mining Engineers, Vol. IX., page 732; also Prof. J. S. Newberry's pamphlet on *The Origin and Relations of the Carbon Minerals*, Annual Report New York Academy of Sciences, Vol. II., No. 9, 1882.)

Productive Localities.—The only place in the United States where graphite is now mined successfully is at Ticonderoga, New York. This property, owned originally by the American Graphite Company, now belongs to the Joseph Dixon Crucible Company, of Jersey City, New Jersey. The American Graphite Company worked the vein deposits to a depth of 600 feet. The Dixon Company now mines a graphite schist 15 feet thick, carrying from 8 to 15 per cent of graphite, practically an inexhaustible supply.

Numerous attempts have been made to work the similar deposits of Pennsylvania and New Jersey, with only partial success. The parties interested in these attempts are: The Pennsylvania Plumbago Company, the Eagle Plumbago Company, and the Phœnix Plumbago Company, all of which have worked deposits in the Pickering Valley, Pennsylvania; the American Chemical Manufacturing and Mining Company, of Rochester, New York, which has worked the deposits of Northern New Jersey; and Mr. A. Z. Ryerson, who in 1882 worked the deposit at Bloomingdale, New Jersey. Mines of merit are known in Georgia and California, but these can not now be worked on account of the expensive transportation.

Ore Dressing.—Several methods (both wet and dry) of dressing the ore have been attempted. In Vol. IX., page 732, Transactions, American Institute of Mining Engineers, Professor Frazer, of Philadelphia, gives a description of the process adopted in the Pickering Valley. The process used by the Dixon Company, at Ticonderoga, owes its success to careful supervision. It is a wet process in which the ordinary practice is reversed, the "tails" being the useful product, while the "heads" are thrown away. All attempts at dry concentration have failed.

Production.—In 1882, the output of the Ticonderoga mine was 400,000 pounds. The outputs from the other mines have been so spasmodic that it is impossible to give them accurately. Probably 25,000 pounds would cover them all, making a total output in 1882 of 425,000 pounds. For 1883, the Dixon Company has arranged to produce 500,000 pounds; and again estimating the product of the others at 25,000 pounds, we have for 1883 a total output of 525,000 pounds. The average spot value may be stated at eight cents per pound.

Kinds.—On account of the peculiar advertising it has had, graphite is commercially known as German black-lead, Ceylon plumbago, and American graphite. German black-lead is a product of Bavaria. It is of the amorphous variety, and is dressed chiefly by washing. Its price depends on its percentage of graphite and the nature of its impurities, varying from $1 to $10 per hundredweight in cargo lots. It is used in the manufacture of pencils, stove-polish, and foundry facings. Ceylon plumbago is mined at Travancore, Ceylon, and is shipped from Colombo to all parts of the world. It occurs in immense veins of great purity. Cobbing and sizing are the only preliminary operations it undergoes. It appears in the market graded according to size, as large lump, small lump, chip, and dust. Its price varies from $2 for dust to $10 per hundredweight for prime lump, in cargo lots. It is used for all the purposes of the trade, except the manufacture of pencil leads. American graphite, from the nature of its occurrence, appears in the market only in the dressed condition. Its price ranges from $2 to $10 per hundredweight wholesale, according to purity and fineness. Fineness exercises considerable influence on the price of graphite, on account of the difficulty of pulverizing it. American graphite is used for all purposes of the trade, and excels all kinds as a lubricant. It is the same geologically, etc., as the Canadian. Before the development of the American and Canadian mines, the Ceylon mineral was the standard.

Analyses.—In 1876, the Canadian government authorized an extended survey and investigation of the comparative merits of the Ceylon and Canadian varieties. The following table of analyses of carefully-prepared samples is from the report of the survey:

ANALYSIS OF CANADIAN AND CEYLON GRAPHITES.

LOCALITY.	Specific gravity.	Volatile matter.	Carbon.	Ash.
		Per cent.	Per cent.	Per cent.
Canada, Buckingham; vein graphite; variety, foliated	2·2689	0·178	99·675	0·147
Canada, Buckingham; vein graphite; variety, columnar	2·2679	0·594	97·626	1·780
Canada, Grenville; vein graphite; variety, foliated	2·2714	0·109	99·815	0·070
Canada, Grenville; vein graphite; variety, columnar	2·2659	0·108	99·757	0·135
Ceylon; vein graphite; variety, columnar	2·2671	0·158	99·792	0·050
Ceylon; vein graphite; variety, foliated	2·2664	0·108	99·679	0·213
Ceylon; vein graphite; variety, columnar	2·2546	0 900	98·817	0·283
Ceylon; vein graphite; variety, foliated	2·2484	0·301	99·284	0·415

These analyses prove the oft-repeated claim of the dealers in Canadian and American graphite that it is equal to the best Ceylon.

Manufactures.—The properties of graphite make it useful for the following general purposes: The manufacture of refractory articles, lubricants, electrical supplies, pigments, and pencil leads. A detailed table of the articles made from it is annexed, with an estimate of the percentage used for each purpose:

PROPORTIONATE AMOUNTS OF GRAPHITE USED FOR DIFFERENT PURPOSES.

MANUFACTURES.	Kinds of graphite used.	Per cent.
Crucible and refractory articles, as stoppers and nozzles, crucibles, etc	Ceylon, American	35
Stove-polish	Ceylon, American, German	32
Lubricating graphite	American, Ceylon	10
Foundry facings, etc	Ceylon, American, German	8
Graphite greases	American	6
Pencil leads	American and German	3
Graphite packing	Ceylon, American	3
Polishing shot and powder	Ceylon, American	2
Paint	American	1½
Electrotyping	American, Ceylon	¾
Miscellaneous—piano action, photographers', gilders', and hatters' use, electrical supplies, etc		¼
		100

The earliest use of graphite was for pencil leads. La Moine cites a document of 1887 ruled with graphite. Its use for this purpose has become so extended that in 1882 over 150,000,000 pencils were made in the world. Previous to 1827, black-lead crucibles were made only in Germany. In that year, the late Joseph Dixon began their manufacture in this country, using graphite from New Hampshire. He afterward saw samples of Ceylon plumbago, and, appreciating its value, he secured a shipment from Ceylon in 1829. This was the first importation of Ceylon plumbago into this country; since that time, its use has steadily increased. In the fiscal year 1882, 16,047,100 pounds of plumbago were imported, most of which was from Ceylon; the rest from Germany.

Graphite has long been used as a lubricant. This is one of its most use-

*From advance-sheets of *The Mineral Resources of the United States*, published by the United States Geological Survey, Department of Industrial Statistics. Albert Williams, Jr., Chief of Department.

Digitized by Google

ful applications, and one which promises most for the future. Formerly, it was offered to the engineer only in the form of a dry powder; now it is compounded, or mixed with fats and oils in many ways, some of which are patented. This use of graphite is attracting the attention of all interested in the problem of the reduction of friction, and promises to outstrip all others. The barriers which have prevented its extensive use in this direction have been the price and the difficulty of securing purity and freedom from all grit. These are now both overcome, the price being now less than 25 per cent of what it was fifteen years ago. The purity, which now is absolute, was then only approximate. For all heavy work, graphite is undoubtedly the lubricant of the future.

The growth of the graphite industry has kept pace with the age, each new development in metallurgy and engineering offering some new field of usefulness for graphite. For instance, it furnishes the pots for the manufacture of cast-steel, and the nozzles and stoppers used in the Bessemer process. It is used in the manufacture of electrical supplies, etc. Fifty years ago, graphite was little known and misnamed. Now, it is of constantly increasing importance. From an insignificant beginning in the present century, the industry has grown to its present proportions. The principal houses engaged in the graphite industry are as follows:

LIST OF AMERICAN MANUFACTURERS.

House.	Location.	Articles made.	Estimated number of hands.

NOTE.—In arranging the matter for this paper, I take pleasure in acknowledging the kind assistance of Mr. W. F. Downs, E.M., chemist of the Dixon Company.—J. A. W.

THE STEEL COMPANY OF SCOTLAND.—The directors' report to the shareholders for the year ended July 12th states that the profits of the year amount to £80,908 0s. 5d., from which fall to be deducted—depreciation, £17,000; interest, £15,525 14s. 6d.—£32,525 14s. 6d., leaving a balance of £48,382 5s. 11d., which, with £3686 0s. 8d. from the previous year, gives £52.068 6s. 7d. to be disposed of. The directors have decided to add £5000 to the reserve fund, which will then amount to £13,000. From the balance of profits, they recommend that £43,612 16s. be appropriated to the payment of a dividend on the paid-up capital of 11 per cent, free of income tax, payable one half on October 9th, and the other half on April 9th next; the balance, £8455 10s. 7d. to be carried forward. The Steel Company of Scotland is one of the largest and most successful open-hearth steel plants in Great Britain.

THE ELECTRICAL TRAM-CAR IN PARIS.—*La Nature* publishes an article from the pen of M. E. Rouby, engineer, in which he gives some electrical and mechanical details concerning the system adopted for propelling the electrical tram-car recently experimented with in Paris. It was one of the largest kind constructed by the Compagnie Générale des Omnibus de Paris, could carry 52 passengers, and was not specially made with a view to electrical traction. The mechanical details connected with the fitting of the dynamo and gearing under the car were designed and carried out by M. Raffard. Under the floor was fixed a Siemens D dynamo, the current being supplied by 80 accumulators placed under the seats. The dynamo was connected by means of a belt and pulley, with differential movement, to an intermediate spindle. Two pinions engaging the two ends of this spindle, two endless chains and gearing, completed the transmitting mechanism. On the day of the trial, the car made a journey of about 32 kilometers, at a mean speed of from 11 to 12 kilometers per hour. The total weight of the tram-car, including 80 accumulators of 30 kilograms each, was about nine tons. The average current was 35 ampères, with an electro-motive force of 165 volts. The electrical work supplied to the machine by the accumulators was therefore 7·7 horse-power for 2½ hours, the duration of the journey, and the accumulators were far from exhausted.

FURNACE, MILL, AND FACTORY.

The Fayette furnace, Michigan, was blown in September 10th, and made its first cast the following day.

Mr. W. S. Armitage, of Detroit, Secretary of the Eureka Iron Company, Wyandotte, Mich., announces that the property of the company, including two blast-furnaces and mills for the manufacture of boiler plate, tank, sheet, and bar iron, knobbling and puddling-furnaces, as well as the foundry cupolas, boiler, machine, blacksmith, and pattern shops, testing-machines, weigh-scales, docks, railroad tracks, locomotives, charcoal kilns, etc., will be sold at Wyandotte on the 10th of October, as the charter of the company expires by limitation on the 24th of that month.

Mr. John Birkinbine, Secretary of the Association of Charcoal Iron-Workers, describes the plant as follows: No. 1 furnace, now rebuilding, is an iron-tapered shell supported on ten tall columns; it will be lined to 12-foot bosh, and is 55 feet high. It will be fitted with fire tuyeres. Blast is supplied by a vertical blowing-engine—blast cylinder 60 inches, steam cylinder 24 inches in diameter, stroke 5 feet; one hot-blast stove, with 24 U pipes, will heat the blast, and three double-flue boilers furnish steam. A double-cage steam-hoist will be provided. The furnace will be fitted with bell and hopper, and be water-jacketed for 11 feet from the bottom. No. 2 furnace is a stone stack 45 feet high, lined to a bosh diameter of 9 feet, and is now in operation, producing 40 tons (2268 pounds) of forge iron daily. The furnace has four tuyeres, to which blast is supplied by a vertical engine; blast cylinder, 60 inches diameter, steam cylinder 20 inches diameter, stroke 5 feet. There is one Player hot-blast stove of 24 pipes. The furnace uses a water-balance hoist. It is operated with charges of 300 pounds of charcoal, with from 550 to 600 pounds of ore, and 25 pounds of limestone as "burden." The average pressure blown is 2¼ pounds per square inch. Casts are made four times daily, and during our visit a cast was run. The consumption of charcoal varies from 1960 to 2100 pounds per ton (2268 pounds) pig-iron. The average yield of the ore is 62 per cent. There are 14 bee-hive kilns of 25 cords each at the plant, but most of the coal is purchased and brought by special cars from the interior of Michigan and from Canada to the furnace, the haul being from 10 to 30 miles, and the freight charges are 1 cent per bushel (20 pounds). The company also obtains the coal from 16 Mathieu retorts at Luther, 250 miles from Wyandotte, the freight in railroad company cars being from 2 to 2½ cents per bushel. The coal is loaded from cars directly into charging buggies. The forge department consists of one run-out fire (6 tuyeres) and 14 single tuyere knobbling fires. These fires are run chiefly on raw pig-iron, although the "run-out" is occasionally used. The company finds it more advantageous to work the pig metal raw. The fires are placed in pairs back to back, and four of them are connected with a vertical tubular boiler. The loupes are shingled into blooms of 150 pounds, under a five-ton steam-hammer.

A dispatch from Chicago states that the North Chicago Rolling-Mill Company has decided to build a $100,000 nail-mill at Bay View, near Milwaukee, and will employ 600 men. The building will be put up at once, and the first nails will be made and delivered by January 1st, 1884.

The *Age of Steel* for September 8th, says that the Missouri Furnace Company is about to remove its blast-furnace from Carondelet, a district of St. Louis, to some point in Alabama or Tennessee. This company has been operating its own furnaces, two stacks, at Carondelet, besides two stacks belonging to the South St. Louis Iron Company. It also operated for several years the two stacks of the Meier Iron Company at East Carondelet. The cause given for the removal is the high freight charges on its raw material. The iron ore has been obtained for the most part from mines on the line of the St. Louis & San Francisco Railroad, fifty to seventy miles from St. Louis, but the freight charge of two cents per ton per mile has brought the cost of the ore to such a point as to leave no profit on the pig-iron.

H. A. Ramsay, proprietor of the Vulcan Iron-Works, of Baltimore, made an assignment September 19th. His liabilities are not known, but he states that his assets will be ample to pay all the debts.

The Atlas Engine-Works, of Indianapolis, Ind., have opened an office and sales-room at 1308 Union avenue, Kansas City, Mo., with A. M. Morse as general agent.

The Troy (N. Y.) *Standard* of September 8th says: The Bessemer Steel-Works will stop for repairs the latter part of this week. The works will remain idle for several weeks. The stoppage is only after a steady run of six months.

The new steel-mill of the Hartman Steel Company, at Beaver Falls, Pa., is completed and working to the entire satisfaction of its proprietors. This is considered a model mill, and has been constructed in the most perfect manner within the past five months. Special advantages are claimed in the economical features of working large sections of billets into various shapes and sizes, which is not feasible in other mills. Buildings are of iron throughout, and machinery, foundations, etc., of the most modern and perfect style. The company is not sparing expense to accomplish great results in the manufacture of low carbon steels. Its wire mill is running to fullest capacity, including the galvanizing department, which has but recently been completed. When it is remembered that these works have been erected within ten months and have already produce nearly ten thousand tons per month, it will be seen that no stagnation is permitted in the management. The capacity, when the works are entirely completed, will be two hundred tons per day of steel, wire rods, and finished wire.

The Lechner Manufacturing Company, of Columbus, O., manufacturers of malleable roller detachable chain belting, has furnished the Columbus & Hocking Coal and Iron Company, Columbus, O., with chain elevators for its four mines at New Straitsville, O. It has also made large shipments to the Ohio Central Railroad Company at Corning, O., these elevators being used for elevating coal. It has also furnished the Farmers & Merchants' Steamboat Company, New-Berne, N. C., and the Neuse River Navigation Company, Kinston, N. C., with its steel roller chain, which is used to propel stern-wheel steamboats, and has received a large order from William Watson, contractor, Chicago, Ill., for shipment to Cairo, Ill., and Charleston, S. C., for package elevators.

The success of the Gates patent pulverizer at the Portland mills, owned by the Portland Consolidated Mining and Milling Company, creates much enthusiasm throughout the Black Hills. The crusher which is manufactured by Messrs. Charles Kaestner & Co., of Chicago, was fully described in our issue of September 1st. We then stated that we would give results of a trial, which are now reported as follows: 2½ tons per hour through a 40-mesh screen; 2 tons per hour through a 60-mesh; and 1½ tons per hour through an 80-mesh screen. The machine shows no indication of wear, and is operated continuously. Mr. Gates, the patentee, is superintending. Messrs. Charles Kaestner & Co., manufacturers, report two sales as the result of the work done by the machine put in Portland mill, to parties in the Hills.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY—TOMBSTONE DISTRICT.

MOUNTAIN MAID.—It is stated that work will shortly be resumed. The drifts of this mine and the Vizina drifts are connected, and the intention is to work the Mountain Maid through the Vizina. This is a great convenience, as the limited area of surface ground at the main shaft of the Mountain Maid necessitates the hauling away of the rock as fast as taken out.

GRAHAM COUNTY.

From the Greenlee Gold Mountain District, about eight miles from Clifton, comes the news of a rich strike. The assays made of the ore found show twelve hundred ounces of silver and twenty-three ounces of gold. A new town-site has already been located. As great excitement prevails in the camp, allowance must be made in regard to the above statements.

YAVAPAI COUNTY.

DOSORIS.—Good ore has been found in the bottom of a shaft now down nearly 300 feet. The mine is pretty thoroughly prospected. Shafts, tunnels, drifts, and cuts have been made to test the size and permanency of the vein-matter. Thus far, the mine has showed mineral all through, and the proceeds from the ore extracted have paid all expenses. At present, high-grade ore is taken from the ledge and prepared for shipment to Pueblo, Colorado.

CALIFORNIA.

MONO COUNTY—BODIE DISTRICT.

BODIE CONSOLIDATED.—During the past week, 137·485 tons of ore were sent to the mill and 156·625 tons were crushed. The average assay value of the pulp was $21.83 per ton; that of the tailings, $4.27 per ton.

STANDARD CONSOLIDATED.—The official report for the week ended September 8th shows that there were extracted and shipped to the mills 1343 tons of ore. The bullion shipment was valued at $19,843.99.

SIERRA COUNTY.

MARGUERITE.—The Downieville *Times* is responsible for the statement that work has been suspended and that attachments and mechanics' liens to the amount of several thousand dollars were served on the property recently. It states that the company owes ten thousand dollars in the county. It is also stated that an offer of $75,000 was made for the Marguerite property a short time ago.

CANADA.

PROVINCE OF NOVA SCOTA.

COXHEATH.—According to reports, work has been temporarily stopped at this copper mine. This is said to be in consequence of the large quantity of ore which has already been raised and banked, the company not having fully decided whether it will ship this ore away or have it smelted at Cape Breton.

PROVINCE OF ONTARIO.

Advices from Cleveland state that H. B. Payne, Stephenson Parke, William Chisholm, and a number of Cleveland gentlemen, have placed a large amount of capital in iron mines in Ontario. The iron range is 90 miles inland from Lake Ontario, and the area is supposed to be in the neighborhood of 60,000 acres, part of which, however, is owned by Canadian and New York capitalists. The mines will be reached by the Central Ontario Railroad, which is now in course of completion, and which will have the entire monopoly of the carrying trade of all the mines. The terminus of the railroad is on Weller's Bay, the best harbor on Lake Ontario, and only 60 miles distant from Oswego, and about 36 from Rochester. Extensive docks and ore-pockets have been constructed to facilitate the shipment of ore to the United States. The ore outcrops at considerable elevation, and, in order to secure a large output from the mines that have been started, it will not be necessary for some time to erect expensive plants. The mines have already been located, and the output the first year the road is completed will be somewhere in the neighborhood, it is thought, of 100,000 tons. The whole matter as yet is in such shape as to give very little idea of the resources of the beds. It will be some time before the Central Ontario Railroad is completed, and until then operations can not be commenced. Samples taken from a number of localities on the range show magnetic and Bessemer ore of the finest quality. The Cleveland syndicate starts out with a capital of $2,000,000.

Phosphate mining in the Ottawa District is vigorously carried on, and the output for the present year will in all probability be larger than that of any previous season. Very little change is noticeable in quotations, the latest being from $14 to $15 per ton delivered at the Canadian Pacific Railroad station at Ottawa.

According to the Montreal *Gazette*, a clumsy attempt to salt a mining property in the Gatineau Valley has recently been discovered. The owners had succeeded in transplanting several hundredweight of the mineral before their fraud was detected.

COLORADO.

CHAFFEE COUNTY.

The new smelting-works at St. Elmo are in successful operation.

CLEAR CREEK COUNTY.

INDEPENDENT TUNNEL COMPANY.—This company was recently formed at Idaho Springs. The property is in the Cascade District, and consists of the Port Jarvis, Boss, Reliable, Chance, Brochu, and Chloride lodes. A tunnel, now started and into the mountain twenty-five feet, will be continued to strike all of the named lodes. All of these lodes are but prospects from 12 to 30 feet in depth. Assays of from $75 to $150 have been made from selected pieces of ore. New buildings are to be erected at once.

CUSTER COUNTY.

BASSICK.—It is reported that this company has at last determined to erect two concentrators with a capacity of over a hundred tons daily. The mill will be located in the vicinity of Blackburn. The mine can produce without difficulty 200 tons of ore a day.

DOLORES COUNTY.

LITTLE MAGGIE.—In cutting through the supposed foot-wall recently, a second body of mineral was uncovered, making the vein 11 feet wide of solid mineral. It contains a body of sand carbonates, galena, and gray copper.

FREMONT COUNTY.

It is reported that the Standard Oil Company has purchased large tracts of land in this county.

ARKANSAS VALLEY OIL, COAL, AND LAND COMPANY.—This company has been incorporated with a capital stock of $3,000,000, in shares of $100 each, and will do business in this county. The directors are also the directors of the Denver & Cañon City Railroad Company, which has also been recently incorporated with a capital stock of $10,000,000. This company proposes to build a broad-gauge railroad from a point just below Colorado Springs to Cañon City. This road is to be run in connection with the Denver & New Orleans. The route has been surveyed, and is said to be shorter by eighteen miles than the Denver & Rio Grande via Pueblo.

GILPIN COUNTY.

BELLEVUE TUNNEL.—A meeting was recently held in Central City, for the purpose of discussing the question of driving the Bellevue tunnel, as proposed by Mr. B. H. Locke and others, from a point on Fall River in a northerly direction under Bellevue, Leavenworth, Quartz Hill, and Gunnell mountains, cutting all the principal gold-bearing veins in Gilpin County. For this purpose, it is proposed to organize a company with a capital stock of $1,000,000, divided into 100,000 shares of preferred stock and 200,000 shares of common stock of a par value of $10 per share, the preferred stock to represent the actual money to be paid into the treasury and expended in the construction of the tunnel, stamp-mills, and general plant, and to draw a dividend of seven per cent. To secure the accomplishment of this, Mr. Locke stated that the company will endeavor to secure the union of the separate mines of the various groups, thereby avoiding all legal trouble regarding the identity of veins and the boundary-lines, and at the same time securing the maximum output of ore from each mine for transportation through the tunnel to mills to be erected on South Clear Creek. The company did not propose mining as a business, but looked for a return for the amount of capital invested from a system of transportation and drainage. The tunnel in being driven three miles in length, will cross 180 patented mines, in addition to numerous unpatented properties and blind veins, or those not cropping out at the surface. The average depth to be attained in running the tunnel half a mile each side of the center of the tunnel is 1600 feet. The veins tapped will be developed and the ore removed by laterals from the tunnel. All blind veins found will be leased to individuals or pools. The tunnel is to be 14 by 12, with a water-conduit on the floor of the same, with double-track its entire length. Mr. Locke's proposition was, that the leading mine-owners should subscribe 100 shares of stock each, thus identifying themselves with the success of the enterprise, which be very justly claims was far preferable to having the scheme carried through by those whose interests might become inimical to them. Mr. H. M. Rogers, Superintendent of the Bobtail Mining Company, and familiar with the country traversed by the tunnel, said that the Bellevue was above comparison with other tunnels of similar magnitude, from the fact of its crossing such a large number of veins in its course.

PRIZE.—A lot of smelting ore was recently sold, which netted $1600. The mill-dirt for the month of August treated at the stamp-mills in Black Hawk yielded 231½ ounces of gold, which brought $16.50 per ounce, a total product for the month of $5413. The company has expended a large sum of money in getting its property properly developed.

HINSDALE COUNTY.

NEW YORK & LAKE CITY.—Work will soon be commenced by this company on the Lookout and Golden Eagle mines.

LAKE COUNTY.

The Leadville *Herald* says that, while several more of the smelters promise to be idle soon, and a number of workingmen are thrown out of employment, the miners of the district are profiting by the ruling low rates for smelting.

COLONEL SELLERS.—The owners have purchased the Little Hope, or, in other words, given the claimants of the Little Hope lode $4000 to quit-claim their alleged claim to the property.

DUNKIN.—The mine during August shipped 160 tons of ore, some of it being of very high grade. So far in September, the product of the mine has reached 65 tons, but the ore is of inferior grade to the yield of previous months. The mine exhibits no particular change, the workings running in and out of ore at irregular intervals.

LA PLATA.—The smelter has blown out four of its furnaces, and only two stacks now remain in blast. They will clean up the supply of ore on hand in from four to six days, and by September 16th the entire works will be shut down. The cause of this suspension is the absence of ore. The management has found it impossible to secure ore, the great output of the district having been secured by the competitive works at Pueblo and Denver. Ore could be obtained from those people who held the key to the situation, but not at figures that would permit the smelter to run at a profit. The sampling-works attached to the smelter will be kept in operation, and ore will still be purchased and received, if it can be got at a reasonable figure, and stored until the accumulations warrant the blowing in of the furnaces again. The product of the La Plata mine will receive a similar disposition, unless the competition for ores should create a price at which more could be made by selling than by reduction at the company's works. The manager stated that, while the outlook was very gloomy, he would continue the improvements just begun at the smelter, and put the establishment in a position where it would be able to compete successfully with any of the Leadville works. With the addition of efficient condensers and the other improvements contemplated, ore could be smelted far more economically than it has been in the past. The La Plata mine is looking and doing as well now as at any time in the past. The new shaft started six weeks ago has been connected with the lower ore-bodies of the mine. The shaft passes through the

Digitized by Google

tunnel about twelve hundred feet from the mouth of the latter. Sinking was prosecuted both from the surface and tunnel level, and a rise was also made from the tunnel to meet the shaft.

LEO.—The owners of this claim, situated on the California Gulch slope of Breece Hill, a short distance east of the Moyer shaft of the Iron Silver Company, have decided to work their property. The shaft at present is down 60 feet, and it is calculated that an additional depth of 300 feet will carry it to the contact, with every probability of disclosing the same ore-chute recently opened in the Moyer shaft.

LIME LODE.—The lessee of this lode of the Iron Silver group reports shipping about forty tons of ore a day. The mine is showing extensive resources. A renewal of the lease for the next six months has been secured. A tunnel is now driving calculated to tap the lower ore-bodies and facilitate the working of the mine.

LITTLE DAISY.—The original Daisy property was located on the discovery of a mineral vein, near the base of the Mosquito range. This vein has a nearly east and west course, confined by granite walls, and was opened by a tunnel about ninety feet in length. The vein-material was found rich in silver existing as sulphurets. After the value of the vein had been determined at this point, a new tunnel was commenced higher up the mountain side, where the vein had left the Archæan rocks and cleft the overlying sedimentary formation. This tunnel has advanced 620 feet, and shows a strong vein the entire distance, with bold ore-chutes at regular intervals. The vein shows great strength, and its width has been determined in but a few places. The metallic minerals of the vein are silver sulphurets, free gold, galena, and iron pyrites, from which very high returns have been received. During the past month, the company erected buildings for the accommodation of its employés, and also to facilitate the workings of the property. During the past week, in making an excavation for an addition to these buildings, a new strike was accidentally made, which promises to eclipse the old property. The laborer engaged in the work had removed but a few shovelfuls of the surface soil, when he struck into a solid mass of decomposed mineral which, on investigation, proved equal in appearance to the ore in the tunnel. Prospecting for the extent of the vein was immediately begun, and in a short time a vein was opened up having a width between walls of about eight feet, with four feet of ore. Samples of the ore were brought to Leadville, and the select material returned 556 ounces of silver and two ounces in gold to the ton, in addition to 38 per cent in lead. Mineral of inferior appearance was also tested, and assays showed it to contain 206 ounces in silver to the ton. It is stated that next year the company will erect a stamp-mill and other necessary metallurgical works for reducing the product of the mine on the premises. In the mean time, the property will be thoroughly explored and developed, preparatory to a large production.

ROBERT E. LEE.—About fifty tons a day of dump material are shipped to the Leadville Gold and Silver Mining Company. The ore ranges in value from twenty to thirty ounces to the ton.

RUBY.—This mine, on Iron Hill, is shipping about twenty tons of ore a day. The product averages ten ounces in silver and sixteen per cent in lead. Drifting to the eastward from the bottom of the shaft is in progress.

PITKIN COUNTY.

The wages of the miners at work on the Porcupine group have been reduced to two dollars a day and board. The price was formerly two dollars and fifty cents. The Silent Friend has reduced wages also to that, and it is likely all other mines will.

CHRONICLE.—The vein is six feet and three inches from wall to wall, and the whole space is mineral. The shaft is down nearly eighty feet, and a drift will be started on the vein running south. Another drift running north will be commenced about the time the mill starts up. There are about five hundred tons of ore ready for treatment, which will occupy the mill about three weeks. The mine will produce forty tons per day, the amount necessary to keep the mill running.

GOLDSMITH.—An assay made on a new class of ore recently struck yielded $276.50 per ton, as follows, 13 ounces in gold and 15 ounces in silver.

TAM O'SHANTER.—It is reported that the miners of this mine, at Ashcroft, are on a strike, and threaten to burn the mine property because of the discharge of Eben Smith, late superintendent, and a number of miners.

SAN JUAN COUNTY.

SAMPSON.—The formation of the recent strike shows black sulphurets, though the ore itself is blue and white quartz, and in some places decomposed. It shows free gold, which is easily discerned, and is beyond all doubt rich throughout the entire vein.

DAKOTA.

GOLDEN SUMMIT.—The mill is to start up shortly. Developments at the mine continue, and it is stated that more extensive reduction-works will be erected this fall.

GREAT WEST.—Work is pushed vigorously at the mine; the twenty-stamp mill will be in operation before the end of the month.

SITTING BULL.—A number of men have been discharged until the litigation pending is settled.

STAND-BY.—The flume destroyed by the recent flood will be restored, and loose machinery and tools that have disappeared will be replaced. It is the intention to run the mill on Stand-by ore and for custom-work.

UNCLE SAM.—Fifteen stamps have been started up and the mill will shortly be in full operation.

GEORGIA.

Most of the mills driven by water-power at the mines in Lumpkin County have been obliged to close down for want of water. It is stated, on what authority we do not know, that the water has not been so low in fifteen years as it is at present. Work at the mines continues and the developments made show most gratifying results in some cases.

IDAHO.

The copper smelter of Bruner, Hennicke & Cranston, at Hailey, will be blown in very shortly. The stack is intended for three furnaces of six tons daily capacity each, but only one furnace of six tons will be erected and operated this year. The smelting firm owns two mines—one on Deadman's Flat and the other on Lost River—from which it expects to extract ore enough to keep the furnace going. Next spring, it will add another furnace to its plant.

BULLION CONSOLIDATED.—The last of the machinery for the concentrator of this company, in Little Smoky District, has been shipped. A strike in the north drift from the bottom of the 100-foot shaft on the Bullion mine is reported, and fine ore is said to be coming out of the other shaft on the same mine. Tunnels are running for the vein on both the Providence and Ophir mines, but they are not in far enough to cut the ledge.

POINT LOOKOUT.—This mine, in Bullion District, on a lode running at an angle and in contact with the Mayflower, was recently sold in Salt Lake City. The property is just west of the Mayflower, higher up the hill, on a ledge which has a good strong vein of galena, tapped in three places, covering a distance of 300 feet on the ledge. This vein has been tapped in one place by two tunnels, each in about sixty feet, and a shaft over sixty feet deep. A streak of galena eight inches wide goes over 400 ounces silver and 70 per cent lead. The ore is similar to the Mayflower ledge. The Point Lookout lies between the Mayflower and the O. K., the last named being a good producer of ore. Mr. Lipman, the purchaser, was one of the pioneers of the Wood River country, having been one of the locators of the Bullion, and was the first superintendent of the company, which he organized to take and work the property. He has sold an interest in the Point Lookout to some New York gentlemen who possess ample means to operate the property on a large scale, and it is the intention to push work on it. It is stated that about $75,000 were paid for the entire claim of 1500 feet in length, which has already been patented.

ROBERT EMMET & FOREST CREEK.—The five claims owned by the company are known as the Forest Creek Nos. 3 and 4, Robert Emmet, Buckeye, and Idaho. On the Forest Creek No. 3, the Buckeye, and Idaho, the holding work only is done; but on the Forest Creek No. 4, there is a tunnel 340 feet long, a shaft 200 feet deep, and about 80 feet of winze. The ledge has been cut at a depth of 150 feet, and bunches of galena found in it that promise much for the mine in depth.

MAINE.

Preparations are making for the extensive development of the iron mine discovered some years since at Webb's Mills, in the town of Casco. A stock company has been formed for the purpose, and a portion of the necessary machinery is already on the ground. Operations will be commenced shortly.

DOUGLASS.—Seven tons of refined copper were recently shipped to Boston.

ROSIER.—At this company's property, at Cape Rosier, they are troubled considerably by water, and will consequently increase the pumping capacity.

STEWART.—The ground in both east and west drifts continues to improve, and development-work is progressing favorably. The open cut is showing good ore and the entire mine is looking well. Both mine and machinery are in shape for future rapid work.

SULLIVAN.—The company has shipped a quantity of ore to Boston for treatment.

MEXICO.

THE ANGLO-MEXICAN MINING COMPANY (LIMITED).—This company has been incorporated in London, with a capital of £325,325, in shares of £5 and £1, to acquire the Yedras silver mine and the ranche known as Valgame Dios, in the State of Sinaloa. The consideration of purchase of the above is £280,325, of which £200 is payable in cash and the balance in fully paid-up shares.

MICHIGAN.

The following table exhibits, in gross tons, the total lake shipments of iron ore from upper peninsula ports the present season, up to and including September 12th, together with the amount shipped from the same ports during the corresponding period of last year:

Name of port.	1882.	1881.
Escanaba	1,274,067	975,811
Marquette	715,585	470,545
L'Anse	46,807	48,087
St. Ignace	33,600	27,564
Total	2,070,059	1,522,007

Showing a decrease of 548,052 gross tons.

ALLOUEZ.—The Houghton *Mining Gazette* says that there is no truth in the report circulating that the Allouez has opened an amygdaloid belt west of the conglomerate that is very rich. Exploratory work has led to finding two amygdaloid deposits west, but at points opened they show little or no copper. If the lodes are further examined, something may be found of value.

BERRINGER.—At this gold and silver location, a shaft will be sunk at least 50 feet, before any rock is taken out and sent away to the smelting-works at Chicago and Newark. This is for the double purpose of testing the question of depth and the quality of the vein-matter. Average analyses will be made as the shaft goes down, those already in hand showing from a trace to something over $300 in gold and silver.

DELPHIC.—The first shipment of ore was recently made.

NORTHWEST REPUBLIC.—No. 1 shaft is down 33 feet in ore, on the foot-wall side, having first passed through 42 feet of sand-drift. From the bottom of this shaft, a cross-cut has been made 21 feet north, all but three feet of which shows clean ore which gives by analysis 67·72 metallic iron, 3·76 silica, and ·052 phosphorus. The last three feet of the drift are in mixed ore, the true hanging-wall not having been reached. Another shaft will be put down some 300 feet farther east, with the view of testing the character and extent of the deposit in that direction. This property is near the Magnetic, and a two-mile extension of the Erie branch will give it the necessary shipping facilities.

MONTANA.

MADISON COUNTY.

The rapid development of the Tidal Wave District is shown by a correspondent of the Butte *Miner* as follows: In 1864, considerable work was done by prospectors who were looking for gold. As the cost of transportation was too heavy in those days, and any thing but gold was valueless to them, the consequence was, that silver, lead, copper, and other minerals were abandoned.. In 1881, working facilities being better, the camp was again prospected for silver, and with good success. At the present time, there are at least a hundred good paying prospects, and new leads are struck every day. The veins are all well defined. This summer, a twenty-ton water-jacket smelter was put up, and is running in full blast on galena and other smelting ores with which this camp abounds. There were also erected oscillating-works, to treat the gold quartz of the numerous gold leads. A ten-stamp gold mill and two arrastras are working in Wisconsin Gulch, and they have plenty of good quartz to keep them running for a number of years to come. The mines are all easy of access, and so far, there has been no trouble with water. The formation is principally granite and slate; and higher up the mountain, the formation is all lime and quartzite.

NEVADA.

CHURCHILL COUNTY.

The San Francisco *Stock Report*, speaking of the discovery of nickel in the northeastern part of this county, says that the location runs from the level ground up to the neighboring mountains, and is in a position that renders the vein easily accessible. The ore occurs in a series of parallel veins quite close together, and pitches at an angle of about forty-five degrees. But little has yet been done toward developing the property—a short tunnel run into the hillside being all the exploration that has been made; but already it has pierced seven distinct, well-defined veins, of an average thickness of 24 inches. This tunnel, together with the little surface exploration that has been made, has exposed to sight what is estimated as at least 1000 tons of the purest, richest nickel ore that has ever been discovered. In this discovery, there is the very unusual combination of large quantity with unusual purity and richness. The first discovery of the metal was made a year and a half ago. As soon as the value of the nickel discovery was realized, experts were at once sent by various would-be purchasers to report on the value of the property. These reports were so favorable that competition among buyers became active, and recently the owners of the property were considering an offer of a quarter of a million dollars.

ESMERALDA COUNTY.

NORTHERN BELLE.—From the very elaborate report presented at the annual meeting in San Francisco, we take the following facts: The mine yielded during the year ended August 31st 19,573 1920-2000 tons of ore, all of which has

Digitized by Google

been milled, besides 504 80-2000 tons of our surplus, making a total of 20,078 tons, showing a gross bullion product of $763,939.32, or $38.05 per ton. An average force of 150 men was employed during the time. Nothing has been done in sinking the main shaft during the year, it having reached a total depth of 800 feet a few months before the last annual meeting. Though the production of the mine has fallen off very materially in the last two months, obliging the company to put mill No. 2 on half-time, still the new development above the seventh is now about 38 tons daily, which is more than sufficient for the requirements of the mill, and will enable a surplus to be stored in the chutes of the mine. Attention during the coming year will be devoted largely to the western part of the mine, which from the adit level down contains a large extent of virgin ground. All prospecting operations in this section, as well as in other parts of the mine, will be pushed with all energy possible, and, there is every reason to hope, with favorable results. The mills have sustained their usual excellent reputation, having performed as much work to the stamp and at a lower rate per ton than in previous years, as will be seen by reference to monthly reports. The low rate of working is partly due to reduced cost of supplies, which are furnished in part and transported by the Carson & Colorado Railroad Company. There has also been a material saving of fuel at mill No. 2 since the new cylinder was put in about three months ago. Mill No. 2 was running full-time up to the last few days, now on half-time, and has been engaged almost exclusively upon the company's ore. Mill No. 1 has been running half-time since March on ore for the Mount Diablo Company. There have been milled during the year 20,078 tons of Northern Belle ore, and 5632 785-2000 of custom ore; a total of 25,710 785-2000 tons, being about the same amount as was worked during the previous year. The Northern Belle ore has yielded 85·3 per cent of the assay value, including all allowances for salt and moisture. Both mills are in a good state of repair, and the amount and quality of the work show their condition and efficiency.

The secretary's statement of financial affairs shows:

RECEIPTS.

Bullion—463 bars, Nos. 5279 to 5741, gross value, $855,988.18, less deductions (which includes freight by express, mint charges, and discount on silver) $136,348.32	$719,639.86
Crushing ores for outside parties	77,453.11
Spring—sale of water	239.28
Drafts outstanding and unpaid September 1st, 1883, constituting our entire indebtedness	22,586.58
Cash on hand September 1st, 1882, $135,972.86, less drafts outstanding at that date, since paid, $23,719.60	112,253.26
W. V. Price, Superintendent, balance in his hands September 1st, 1882, since paid	54.59
Total	$932,226.68

PAYMENTS.

Dividends—eight—Nos. 64 to 71, of $25,000 each, equal to fifty cents per share	$200,000.00
General expense—salaries, insurance, etc	70,675 14

Supplies at mine	10,969.86
Water-works	25,000.00
Oats and hay	107.25
Total valuation	$437,410.41

EUREKA COUNTY.

EUREKA TUNNEL.—The semi-annual statement to the stockholders shows that, since March last, the ore extracted from the mine for the six months ended August 31st amounts to 1425½ tons, of an average assay value of $63.87, giving us a net product at furnace of $52,113.99, approximating $36.57 per ton. The bulk of this was taken from the hard vein forming what is known as the Addison chamber, and called chloride ore; the less quantity from the soft vein, east of and running parallel with it, called carbonate ore. The exploration of the mine to a depth of 150 feet below the tunnel level proves the continuity of the ore-body first found in the south drift from the main tunnel. We have made connection between it and the Addison chamber, while, by drifts, winzes, uprises, and stopes through the carbonate vein, we prove its identity with the vein first found in the old north workings, about 850 feet in from the tunnel opening. Above the tunnel level, we are still following chloride ore, and have hopes of it making in larger deposits than now showing, and all signs known to miners indicate a greater concentration and stronger ore-bodies below. The necessity for revenue to meet the expense of prospecting and opening this valuable property compels the employment of a large number of miners in the ore at hand, which, existing in limestone irregular and scattering as it now is, makes its extraction slow and expensive, but when making in large chambers, such as the Addison, paying well. The financial statement shows the expenditures from March 1st to September 1st for sundry expenses to have been $53,365.64. The receipts were: Net product of ores smelted at furnaces—1425½ tons, $52,113.99; received from El Dorado Consolidated mine for hoisting and supplies, $662.60; received from tributaries for sundry supplies, $130.54. Showing in excess of expenditures, a balance of $460.51.

STOREY COUNTY—THE COMSTOCK LODE.

The outlook throughout the Comstock is more favorable than it has been in many months. In the Union Consolidated, during the past week, the south drift on the 3000 level has passed through a series of streaks of quartz, some of which contained good ore. The drift is now out some 60 feet, and the face again in vein porphyry. The joint Sierra Nevada winze below the 3000 level is down between 53 and 55 feet. It is passing through streaks of metal-bearing quartz that have a slight dip to the east. These streaks probably belong to the east side of the body of quartz cut on the 3000 level by the main west cross-cut. Owing to the presence of the quartz, the ground blasts badly, blowing out in pot-holes. At all points on the 3000, there is an increase of quartz, which makes its appearance in the main veins, and all these streaks contain more or less metal.

In the Gould & Curry, lying to the east on the 2500 level, is exposed a body of quartz of fine appearance that was 180 feet wide where cut through by east cross-cut No. 2. This quartz was also cut by east cross-cut No. 1. The cross-cuts show that the body of quartz is making in strength and width toward the south, and another cross-cut (No. 3) has been started at a point 200 feet south of No. 2. This is now out 25 or 30 feet.

At the Hale & Norcross, they are fast nearing their 2700 level, at which point a station will be made and cross-cutting begun. The ore-seams still hold quite strong in the bottom of the winze, and give promise of ore being found in the cross-cuts.

WHITE PINE COUNTY.

STAR.—The White Pines *News* reports that the old board was re-elected, and, it is presumed the old officers also, at the recent meeting held in San Francisco. It is further stated that L. M. Foulke was appointed superintendent, but this is mere conjecture. What they want of a superintendent just now is not easy to see. But what they are badly in need of is a vigorous and plethoric paymaster, to liquidate their indebtedness, which seems to increase as rapidly when the property lies idle as when it was in operation. Following is a summary of the liabilities and assets, taken from the books:

LIABILITIES.

Old pro rata indebtedness at mine	$17,606.95
Old pro rata indebtedness at San Francisco	3,483.92
Old pro rata indebtedness of B. S. Coffman, Superintendent.	4,906.06
Total pro rata indebtedness	$25,999.93
Indebtedness at mine, present year	34,406.57
Indebtedness at San Francisco, present year	2,285.17
Outstanding drafts of L. M. Foulke	13,112.85
Old overlying indebtedness at Wells, Fargo & Co.'s bank, secured by mortgage, with interest	12,237.85
Overdraft at Wells, Fargo & Co.'s bank, present year, secured by mortgage	40,476.63
Cash owing to Secretary, August 25th, 1883	16.50
Total indebtedness	$128,535.40

ASSETS.

Consists of property at mine and mill as per inventory of superintendent on August 25th, 1883, valued at	$82,594 61

NEW HAMPSHIRE.

CRANE.—A vein of native silver is reported to have been discovered recently at this mine at Dalton.

NEW JERSEY.

NEW JERSEY IRON COMPANY.—For some months past, prospecting for ore with a diamond drill upon the Port Oram property has been done with varying prospects of success. It is stated that the company has struck a very promising vein, the drill having gone through about twenty-five feet of vein-matter, of which fully fifteen feet is pure ore. The company is removing the drill and will prospect in another location.

NEW MEXICO.

BILLING SMELTER.—The smelter was recently started in Socorro, said to be the largest in New Mexico, and equal to those of Pueblo, Denver, or Leadville. A railroad track two and a half miles in length has been laid to the smelter, to connect with the Santa Fé road, and three thousand tons of ore have been hauled a distance of thirty miles from the Billing mine in the Magdalena Mountains to the smelter. Gustav Billing, the sole owner, has invested $290,000 in the construction of the works. Mr. Billing erected his smelter at this point because fuel was very accessible, the coke being drawn from the San Antonio coke-ovens eleven miles distant. The miners have a great deal of confidence, and are now sending in ores and samples. Four hundred bars of bullion were turned out in twenty-four hours.

CARNERO.—The main shaft is to be sunk to a depth of 300 feet. This mine has already produced a large quantity of ore, carrying from 50 to 100 ounces in silver to the ton. Two car-loads have been shipped. There are over 200 feet of underground work done in shafts and levels. As soon as work is resumed on this mine, regular shipments will be made to the Billing works.

MAYFLOWER & CLYDE.—A five-stamp gold mill is to be built at San José Creek, near the first crossing from Fort Bayard, in connection with these mines. The owner of the mines recently, while in the East, made arrangements with St. Louis capitalists, giving them a half-interest in his mines, in consideration of their putting in the mill as stated, giving him a half-interest in the same and furnishing sufficient means to properly develop the mines and take out ore with which to start the mill. Work is to be commenced at once.

UTAH.

BOX ELDER COUNTY.

TRUE FISSURE.—The company is making regular shipments. As the working tunnel gains in length and depth, the quality of the ore and size of the vein increase. The first-class ore now assays over 200 ounces. The company is about to put in a concentrator to handle the 4000 tons of second-grade ore on the dump. The design is to concentrate about three tons into one, which will give them a very handsome and salable ore.

JUAB COUNTY—TINTIC DISTRICT.

There are extensive iron mines in this district, which not only supply the smelters near Salt Lake City with fluxing iron, but at present are sending three car-loads daily to Hailey, Idaho, for use in the smelters.

MAMMOTH.—The Salt Lake *Tribune* says: It is hoped that the affairs of this company will soon be adjusted, and the extensive mines and reduction-plant will again resume operations. Mr. Goodhart, of London, is here for the purpose of arranging affairs with such end in view, and the books and papers are under examination, that he may come to a full knowledge of the situation; and some decision will probably be arrived at soon.

TOOELE COUNTY—CLIFTON MINING DISTRICT.

HAVANA.—Articles of incorporation have been filed by the above company. There are 300,000 shares, par value $10, of which $90,000 are treasury stock. The property consists of the Royal Havana, the More, and Castle, three locations making a plat 1500 feet square, about fifty acres, on the eastern slope of the Deep Creek Range, a thousand feet or so above the desert, near the old overland stage-road, perhaps 150 miles westward of Salt Lake City. The formation is granite. The ledge is in the Havana, strikes east and west, dips from the north about 45 degrees, crops out nearly the whole length of the location, is five feet thick, straight and regular, and has a true quartz gangue. The ore is a silver ore, and it has been found at several points on the surface rich enough to ship. A shaft has been put down 300 feet, and the water is beginning to come in. Levels have recently been started from the 160 and the 250-foot stations, each way. These are to be driven by double shifts. The shaft is expected to soon furnish enough water for a hoisting-engine. Water for reduction purposes is within ten miles of the mine, and mine timber within twelve miles.

UTAH COUNTY.

SPANISH FORK MARBLE COMPANY.—Satisfactory tests having been made of the mottled or concretionary marble from Spanish Fork Cañon, a company has been incorporated in New York by the above name, for the purpose of working the quarries and shipping the marble East. Hon. Samuel Foster, of Troy, N. Y., is President. It is the intention of the company to use machinery as soon as the quarries are opened enough to justify the expense. It is capable of fine polish, and it can be successfully used for various purposes. The cost of shipping to New York will be about $25 per ton. It is very probable that extensive marble-works will be erected in Salt Lake City before long for the purpose of sawing and polishing by machinery; but at present a number of car-loads will be sent to New York and Philadelphia to be thoroughly tested.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Sept. 21.

The Leadville stocks have been the main feature in the mining market this week, and they have been very actively dealt in at strong prices. Little Chief has shown the most strength, while Amie leads in the transactions. Outside of these stocks, Hall-Anderson was very largely dealt in, and at one time was quite strong, but declined at the close. The fancy stocks came in for a good share of the business, but they record no material change in price, being generally irregular. The total number of shares sold aggregates 236,335, as against 165,926 last week.

The Comstock shares were very quiet at steady prices. California sold to the extent of only 300 shares at 18c. Consolidated Virginia was moderately dealt in and was weak; it sold from 54@45@49c. Union Consolidated sold at $4.75. Ophir was quiet and steady at $3.25. Savage sold at $1.90. Sutro Tunnel was very quiet and was irregular, selling from 20@18@19c.

The Leadville stocks were quite active and strong. Amie was very actively dealt in and was irregular, selling from 23@18@20c. Regarding the prospects of the mine, it is stated that the northern portion of the claim is looking quite well and that there are prospects of the property opening up a strong ore-chute. Chrysolite was strong, with an active business, selling from $1.15@$1.35. Dunkin sold from 35@32c., with a business of 1200 shares. Breece was quiet and irregular, selling from 19@16@18c. Iron Silver was steady, under a small business, selling from $3.10@$3.05. Leadville was very strong, selling from 40@53@50c., with moderate transactions. Little Chief was very active and strong; it sold from 59@88@87c. Little Pittsburg was quiet and strong, selling from 60@67c. Climax was strong, with a small business, selling from 9@13@12c.

The Bodie stocks were very quiet at steady prices. Bodie Consolidated was weak under a small business, selling from 85@75c. Standard was quiet and steady, selling from $5.50@$5.75.

The Tuscarora stocks were almost neglected. Belle Isle sold at 22c. Navajo was very quiet at $2.80. Elko Consolidated was fairly dealt in and was steady, selling from 11@10c.

In the miscellaneous list, Alice was quiet and steady, selling from $2.25@$2.40. The future of the Alice is watched with unusual interest. The mine, we presume, must have paid its floating indebtedness and must be in a fair way to cancel the debt of $150,000 contracted to pay for the Magna Charta. The principal drawback in connection with the enterprise is the condition of the two mills, which must suffer frequent stoppages to make repairs. We understand that samples of ore have been sent to the Geddes & Bertrand mill, to test the leaching process, and that the results have been pronounced very satisfactory, particularly so far as the extraction of a high percentage of gold is concerned. The managers will probably have to accumulate funds to build a new mill with, to replace the old one, and probably Butte will then have its first leaching-mill.

Bassick was quiet and steady at $9. Eureka Consolidated suffered a decline from its strong prices of last week; it sold from $6.25@$6.13, with a small business. Green Mountain was quiet and steady at 70c. Hall-Anderson was very active and was quite strong at one time; it sold from $1.15@$1.30@$1.20. Horn-Silver was quiet and steady, selling at $7. Northern Belle was irregular, under a small business, selling from $5.75@$6@$5.63. Robinson Consolidated was very active at irregular prices; it sold at 37c. last Saturday, then up to 50c. on Monday, down to 46c. on Tuesday, up to 48c. on Wednesday, back to 42c. yesterday, and was steady to-day at 44@45c. Sierra Grande was quiet and steady at $1.10@$1.15.

Barcelona was fairly dealt in, and was weak, selling from 45@36c. Bashaw sold at 25c., with a small business. Decatur was quiet and steady at 2c. Eastern Oregon was moderately dealt in, and was steady, selling from 45@46c. Harlem sold at $1.15. Oriental & Miller was moderately active at steady prices, selling from 10@12c. Sonora Consolidated was very active, at irregular prices; it sold from 28@33@28c., with a business of 63,200 shares.

The reports from the Ontario mine are very encouraging. New ore-bodies have been opened out, and the prospect-work on the recently acquired Daly claim—a shaft now down 200 feet—has opened out very well.

It is reported, on what authority we do not know, that the Sierra Apache, Sierra Bella, and Sierra Grande companies will be consolidated, and that the new company will be formed on a basis of six million dollars, with six hundred thousand shares. The annual meeting of these companies will be held at Lake Valley, September 26th, and if such a proposition is to be presented, it will be then and there discussed. According to the reports made of the rich discoveries in the different mines, they were entitled to handsome profits. As yet, these expectations have not been realized. The Sierra Apache and Sierra Bella have paid no dividends, and but $600,000 have been paid to the fortunate investors of the Sierra Grande Company's stock.

MEETINGS.

Ophir Gold Mining Company, No. 30 Cortlandt street, New York City. Annual meeting of stockholders and election of trustees, October 2d, at twelve o'clock M.

Todos Santos Silver Mining Company, No. 18 Wall street, Room 10, New York City. Annual meeting of stockholders and election of trustees, October 3d, between 12 o'clock M. and one o'clock P.M.

DIVIDENDS.

The Crescent Mining Company, of Utah, has declared a dividend of five cents per share, or $30,000, payable September 30th.

The Hope Mining Company, of Montana, has declared its regular quarterly dividend of $1.50 per share, or $11,304, payable at the office of the company, No. 417 Olive street, St. Louis, on October 2d. This carries the amount of dividends paid to $113,035.50.

The Iron Silver Mining Company, of Colorado, has declared a dividend (No. 12) of twenty cents per share, payable October 5th.

The Mount Diablo Mill and Mining Company, of Nevada, has declared a dividend (No. 2) of twenty five cents per share, payable on the 25th day of September.

PIPE LINE CERTIFICATES.

Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows for the week:

Last Friday, oil opened at $1.12, sold down to $1.11⅛, rallying late Saturday afternoon to $1.15⅝. Monday morning, it opened at $1.16⅛, but broke away to $1.13⅞ during the day. Tuesday, it sold up to $1.15⅛. Wednesday, it was down to $1.14, at which price it opened Thursday, rallying to $1.14⅞ at the close, with a strong undertone to the market. This (Friday) afternoon, at two o'clock, it is up to $1.17. The situation in the field is bullish. The increased number of wells in Balltown and Cooper tract adds very little to the aggregate production, showing that those pools are limited. The excess of deliveries over runs for the first eighteen days of this month was 222,000 barrels. This represents the decrease in stocks for this period, and shows the heavy accumulation of oil that has been going on in the past, which has been followed, for the first time in seven years, by an important decline. Refined oil is firm at 8⅝, and charters for export continue large.

The advance Thursday afternoon and Friday followed the announcement that Howe Oil Company's No. 5 and No. 7 wells were in the sand and making a good showing. Though the situation is bullish, large traders in Oil City sold freely on the theory that the several wells that were expected in this week would cause a break in prices, but they found that oil was too firmly held and the attempt to buy produced a sharp advance this (Friday) morning.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Sept. 15.....	$1.11⅝	$1.15⅝	$1.11⅜	$1.15⅛	3,256,000
17.....	1.15⅝	1.15¾	1.13⅞	1.14¼	3,566,000
18.....	1.14⅝	1.15⅛	1.13⅞	1.14⅜	4,153,000

21.....	1.15¼	1.17¼	1.14¾	1.15¾	3,409,000
Total sales.					17,706,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, September 20.

The market for copper stocks the past week has shown a good degree of firmness as to prices, although not much activity, and good stocks are in demand at the quotations of last week, while, in one or two instances, a slight advance is noted. The firmness of ingot copper is one of the encouraging features, and there are indications of higher figures in the near future, and this, of itself, serves to impart confidence to buyers of such mines as Calumet & Hecla, Quincy, and others, which pay, or are on the eve of paying, dividends. At the same time, there is as yet no disposition to take hold of the speculative or non-dividend-paying stocks; but this will come by and by. In silver stocks, there is but little doing, and it would seem as if the public generally had about as much of these ventures as they care to hold; for there are more sellers than buyers, and prices do not improve under such circumstances. At the Mining Board, prices continue to decline, and the few specialties dealt in heretofore have nearly faded from sight.

Calumet & Hecla is very steady at $245, and orders for any considerable amount could not be filled at this price. There is a firmer tone to Franklin, with sales at $11@$11½, and but little offered in the market. It ought to sell at higher prices, in view of its prospects of becoming dividend-paying in the near future. Quincy was a little heavy early in the week, and sold at $51; but later, orders coming in freely, advanced the price to $54¼@$54½, with later sales at $54, closing at $54 bid. Osceola was very steady at $18. A dividend of 50 cents per share is announced. Pewabic sold at $3@$3¼, closing sale at $3. In the silver stocks, Bonanza advanced from $1⅞@$2¼, with later sales at $2⅛, at which it is offered, $2 bid. Catalpa declined to 35c. Harshaw, $⅝@$⅞, sales. San Pedro, 15c. At the Mining Board, Bowman Silver Company, which has ruled steady for the past few weeks at 16@17c., declined to 8c. on rumors of another assessment. Massachusetts & New Mexico was dull at 4@5c. Sullivan is quite firm at 90c. regular, to 95c., buyer's option. Dunkin firm at 30c. bid. The rest of the market is dull and featureless.

3. P.M.—There was nothing done in copper at the afternoon Board. Closing prices were: Calumet & Hecla, $244 bid, $245 asked. Atlantic, $10 bid, $12 asked. Bonanza, $1⅞ bid, $2⅛ asked. Franklin, $11 bid, $12 asked. Osceola, $17 bid, $18 asked. Quincy, $54 bid. Silver Islet $2½ bid.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended September 21st, as compiled from various sources, amounted to $246,662, as against $181,300, reported for the previous week. The receipts from January 1st, 1883, to date are $8,234,936.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended September 15th	$166,300
Corresponding week last year	344,650
Since January 1st, 1883	9,995,066
Corresponding period last year	43,970,917

Imports.

Week ended September 15th	$262,357
Corresponding week last year	60,474
Since January 1st, 1883	10,729,328
Corresponding period last year	2,667,812

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 3½ per cent. During the week, the bank gained £96,000 bullion, and the proportion of its reserve to its liabilities was raised from 46¼ to 46⅝ per cent, against 39¾ per cent a year ago.

Purchase of Silver for Coinage.—The superintendent of the Philadelphia Mint has been authorized to purchase 50,000 ounces of silver for coinage into dimes

METALS.

NEW YORK, Friday Evening, Sept. 21.

Copper.—We seem to be fairly entering the usual period of prolonged negotiation between the mines and the manufacturers. The former profess to believe 16c. the figure which the situation will warrant, while the latter insist that they will not pay more than 15c. This maneuvering will probably continue for some time. First hands are not selling, while consumers are buying only to cover immediate wants, and there is so little Lake in the market that what little is obtainable and is wanted brings slightly higher prices, 15¼c. being asked. The Lake mines are certainly in a much better position this year than they have been, in that there is no heavy pressure of outside copper. Consumption is fair, though it will not quite reach last year's total. Good authorities place it between 70 and 72 millions. In sympathy with Lake, other brands are firmer, the best kinds being held at 14¾c. We quote 14¼@14¾c.

London shows a slight weakening in Best Selected, which is cabled £68 10s. f. o. b., while Chili Bars remain at £63 5s.

According to the Board of Trade returns, the imports and exports of copper for Great Britain were as follows:

	Jan. 1 to July 31. 1883. Tons.	1882. Tons.	1881. Tons.
Imports:			
Pure in pyrites	11,002	11,151	9,558
" precipitate	14,733	12,072	13,266
" ore	10,110	9,903	10,504
" regulus	6,468	5,073	4,059
Bars, cakes, etc.	22,540	22,642	20,004
	64,853	60,841	57,391
Exports:			
Raw (English)	11,049	8,085	12,575
Sheets	10,149	10,113	9,048
Yellow metal at 60 per cent	7,779	7,395	5,847
Brass at 70 per cent	2,215	2,128	2,077
	31,192	27,721	29,547
Foreign	8,289	7,881	9,395
	39,481	35,602	38,942

Tin.—Arrivals continue on a liberal scale, 400 tons having come during the week. There is a fair jobbing demand. We quote spot, large lines, Straits or Malacca, 21@21⅛c., and Australian, 21@21⅛c. London cables £93 17s. 6d.

Lead.—Beyond jobbing sales of Common at 4·32½@4·35c. and a small lot of Refined at 4·35c., there is nothing to report. It is given out that one of the more important holders has sold to another. Otherwise, there is no change to note in the situation.

Messrs. John Wahl & Co., of St. Louis, report the following by wire on that market:

Our market is firm but quiet; 130 tons of ordinary Missouri have been sold here to Eastern consumers at 4c.; also, during the early part of the week, 200 tons of Refined at 4·05c.; and on Thursday, 130 tons of Refined at 4.05c., delivered at buyers' works.

Messrs. Everett & Post, of Chicago, send us the following dispatch:

Our market is dull and quiet, with prices unchanged, and nominally 4·10c. There has been an increased demand for spot lead during the past few days. There are, however, no large buyers in the market.

Spelter.—There is nothing new to report. The market drags along, with ordinary Domestic nominally 4⅛c.

Antimony.—Stocks here are limited. We quote 9⅛c. for Hallett's and 10¼c. for Cookson's. A circumstance which tends to restrict the sale of antimony is the increased quantity of antimonial lead which desilverizers and refiners of base bullion place in the market. The use of this antimonial lead avoids much of the waste attending the melting together of the pure antimony and the other metals entering into type-metal and other alloys.

Quicksilver.—From London, Messrs. French & Smith report, under date of September 6th:

A steady business at the lower quotations, namely, £5 7s. 6d. per bottle. The imports and exports January to July (seven months) were, by the Board of Trade returns:

	1883. Pounds.	1882. Pounds.	1881. Pounds.
Imports	3,927,270	3,149,240	3,438,467
Exports	2,244,205	1,608,353	956,718

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Sept. 21.

Mr. Edward J. Shriver, Secretary of the Metal Exchange, publishes the following returns from 108 furnaces for the 1st of September:

Grades.	Stocks Aug. 1.	Stocks Sept. 1.	Prod. July.	Prod. Aug.
No. 1	20,741	21,840	19,700	20,025
No. 2	26,348	25,205	8,095	7,048
Bess., Forge, and lower grades	54,667	46,146	11,207	8,966
Not specified	11,378	12,372	7,155	11,832
Total	111,134	105,563	46,157	47,871

According to the Board of Trade returns, the exports from Great Britain to this country were as follows, for the first eight months:

	1881.	1882.	1883.
Pig-iron	265,887	241,780	198,175
Old iron for re-manufacture	59,461	64,581	37,324
Steel unwrought	74,814	112,825	24,598
Tin-plates	113,512	148,671	141,794
Hoops and sheets	23,782	24,065	22,820
Bar, angle, bolt, and rod	8,364	14,753	6,703
Railroad iron	216,125	155,408	49,827

American Pig.—The situation has, if any thing, grown worse, the transactions being on a very restricted scale. While it is true that the production is restricted and that the stocks in the hands of consumers are undoubtedly much lower than they have ever been known to be, the requirements of consumers are not alone artificially-reduced, but must be in reality considerably less than has been generally believed. As the majority of the dealers who supply this market are strong, and as many of them are probably delivering the bulk of their make on contracts, there are not many signs of weakness, but it is evident that this state of affairs can not continue long without carrying down or forcing the less favorably situated out of blast. The developments of the next few weeks will decide what pressure will be applied. Our quotations remain unchanged, with the market, however, in buyers' favor.

Transactions during the week have been on a moderate scale. We quote No. 1 Foundry, $21.50@$23; No. 2, $19@21, according to quality; and Gray Forge, $18.25@$19.50, all at tide-water. Bessemer Pig is lifeless, and Spiegeleisen is quiet at $30.50@$30.75 for 20 per cent. Low grades are dull at $25@$25.50.

At the Exchange, the following transactions were recorded:

Monday, 100 tons No. 1, October, $21.62½; 100 tons No. 1, November, $21.87½. Tuesday, 100 tons No. 1, January, $21.50; 300 tons No. 1, February, $21.50; 100 tons No. 1, December, $21.62½; 100 tons No. 1, December, $21.50. Wednesday, 200 tons No. 1, October, $21.87½; 200 tons No. 1, December, $21.62½; and 100 tons No. 1, February, $21.62½.

Scotch Pig.—There is very little that is new to report. Freights have advanced to 6s.@6s. 6d.

We quote ex ship and to arrive: Coltness, $23.25@$23.50; Langloan, $23@$23.50; Summerlee, $22.50@$23; Dallmellington, $20.50@$21; Eglinton, $20@$20.50; and Glengarnock, $22@$22.50.

At the Exchange, the following lower cable quotations were received: Coltness, 58s.; Langloan, 57s. 6d.; Summerlee, 56s.; Gartsherrie, 56s.; Glengarnock, at Ardrossan, 54s. 6d.; and Eglinton, at Ardrossan, 47s. Warrants to-day were 46s. 1d.

Rails.—There is no business to report, and the fact that at least one Eastern mill has few new orders for winter delivery is an indication of the fact that the productive capacity is considerably ahead of the demand. We understand that a willingness is shown to obtain orders even at very close figures. We quote $37@$37.50 at mill.

Old Rails.—The quantity of old rails available is slight, while there are a number of inquiries for round lots, with no tendency to business. We quote $23.25@$23.50.

Scrap.—Some business has been done in small lots. We quote, No. 1, $22.50@$23 ex ship.

Philadelphia. September 21.

The Eastern Pennsylvania iron trade has not yet escaped from the dull rut in which it has been confined for the past few weeks. Business continues of moderate proportions, and the efforts of makers of pig-iron to sell large quantities have not met with much success. The trouble is not with prices, but with demand, and the uncertainty as to its volume later on. Production keeps up to the average, but is not gaining. Stocks are slowly declining, and the supply in second hands continues very light. None of the inducements that have been offered during the past few days has led to heavy transactions, but there

are brokers who look for heavy business in a few days, especially in the inferior brands. Buyers are waiting for an improving tendency, before covering requirements, and it is probable that, when any impulse is imparted to the market, demand will assume a shape which will make prices better for the time being. Among the sales heard of this week, were a number of 50 to 100-ton lots at $22. Very little iron sells above this, and more below. In No. 1, the lowest sales heard of have been at $21. A fair amount of No. 2 was moved this week at $19.50 ; $20.50 represents selling prices for the best. A few lots were ordered at $19. The cheap makes of Gray Forge sell at $17 at furnace, but the special makes are bought at a little under $19. Fair inquiries are reported for standard brands of Gray Forge, but the actual business transacted is still below the average of the season. A few brokers are endeavoring to unload large stocks of mill irons, and expect to sell this week. Buyers of Bessemer iron have made inquiries for upward of 20,000 tons ; but no sales have been consummated, because of the refusal of sellers to meet buyers' terms. Offers are made at $20.50. A good deal of Spiegeleisen is wanted, but it is not probable that buyers will pay the prices asked ; $30 is the highest figure that will be willingly paid.

Muck Bars.—Sales of muck bars have been made at $33.50, with $34 asked for some makes.

Blooms.—A retail trade has been done in blooms at $57 for charcoal.

Merchant Iron.—An improving demand has been developed this week for merchant iron, but it is made up of small lots altogether, large buyers holding back for lower rates. Manufacturers are making no efforts to do business at the low prices offered, but are satisfied to sell iron in a small way at present prices. Ruling rates are 2·15c., with some business at 2·20c., and offers at 2·10c. for large lots. Common iron has sold at 1·90c., with some makes held at 2c. Inquiry is very active and large sales probable at the former figure. Lots of Western iron are offered, and are unsettling the market.

Sheet-Iron.—Card rates are unchanged, and shadings are reported on large lots which are taken for November delivery. Stocks are light, especially in thin sheets. Discounts on best galvanized, 40 per cent.

Plate and Tank Iron.—All manufacturers report an active demand in both retail and wholesale way, and mills are well supplied with orders for weeks to come. Prices are firm in all, excepting large lots, in which concessions are still to be had. Boat Plate, 2·35c. ; Ship Plate, 2·40c.

Structural Iron.—The favorable condition of the structural iron interests continues, and mills are busy with orders for future delivery at 2·40@2·50c. for Angles, and combination prices unchanged. Two or three inquiries have just been received for 100-ton lots.

Steel Rails.—No new business of importance has been reported, though negotiations are pending for large lots at $36@$36.50 offered. As soon as the present rush of small orders is out of the way, makers will talk business in a large way, and it is said, by the representatives of buyers, that steel rails will be placed at their prices, which are $35@$37 for winter deliveries. Ordinary lots are taken at $37@$38.

Old Material.—The same condition of affairs is to be reported in old material. Old rails are offered from the South at $23.50. Double-heads can be had at $26 for shipment. Buyers do not seem disposed to place orders at present prices.

Scrap.—Scrap iron is without change. Good selected yard lots are in active demand.

Pittsburg. September 21.

The Pittsburg iron market has not developed that improvement which was expected a week or two ago, and on the strength of which a number of large transactions took place early in the month. The supply of iron seems to be in excess of requirements, but competition is restricted by the fact that outside furnaces can not ship to this point and compete with home furnaces. The cutting which has been indulged in has been trifling, and very little outside iron has been bought, although, from all indications, the offers pending for supplies may be accepted. The dullness is attributed to the uncertainty of the demand for finished iron. All mills are running, but the local furnaces meet the requirements. Prices are slightly lower than last week. Neutral Mill Iron, $17.50 @$18 ; Red Short, $18 ; Foundry, $19.50@$22, according to ore; Foundry Charcoal, $26. A few manufacturers are buying heavily, while the greater number are purchasing for immediate requirements.

Sales of Muck Bar are made at $33.50@$34.

Manufactured Iron is 1·80@1·90c.; sales have been heard of at 1·75c., and efforts are made to sell iron in the interior of the State in competition with Eastern mills.

Plate Iron is 2·50@2·60c. Several large orders have been placed, and inquiries for this and structural iron are improving.

The sheet-iron mills are all busy, with orders for a few weeks to come, and demand seems to be equal to capacity. No. 24 sheets, 3·40@3·60c. card.

The demand for Nails is not active enough to prevent cutting of rates, and prices have been as low as $2.60 in heavy lots.

Discounts on Wrought Pipes are 75 per cent, and on Tubes, 60 per cent.

Merchant Steel, 11@12c. The demand is improving. Machinery, 6½c. Negotiations are in progress for large supplies of steel, but the prices are not named. Heavy sections of Steel Rails are selling at $37.50@$38. Inquiries for winter and spring deliveries at $36.50@37 ; Crop Ends, $24.50. Card rates for Spikes, 2·60c.; Splice Bars, 1·90c.; Bolts, 3@3·20c. A good deal of inquiry prevails for Old Rails. American, $24 ; Car-Wheels, $20 ; Old Axles, $33.50 ; Railroad Scrap, $23. The week has been dull, and the volume of business below the average for the season.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Sept. 21.

Anthracite.

The work of distribution of anthracite coal to individual consumers for domestic purposes in anticipation of the coming cold weather has begun, and is making itself felt in an increased inquiry for stove coal. The dealers will soon find inroads made on their yard stocks, and some of them will probably be forced to replenish before the time when, as usual, prices fall off, which is toward the end of November. October is looked forward to as the most active month in the year, and indications, so far as domestic sizes are concerned, give rise to the belief that it will be so this year. Other sizes are occasionally in excessive supply, and need active pushing to keep them from clogging the market.

Mr. John H. Jones, official accountant, has issued the following statement of the anthracite coal tonnage for the month of August, 1883, compared with the same period last year, this statement including the entire production of anthracite coal, excepting that consumed by employés, and for steam and heating purposes about the mines :

	August, 1883.	August, 1882.	For year 1883.	Compared with 1882.
Phila. & Reading RR.	1,317,954	694,410	5,989,690	I. 1,735,106
Central RR. of N. J.	*	412,370	1,745,399	D. 971,416
Lehigh Valley RR.	†615,612	576,511	3,962,052	I. 217,135
Del., Lack. & W. RR.	557,487	482,927	3,202,202	I. 258,882
Del. & Hud. Canal Co.	‡361,281	298,583	2,171,705	I. 212,819
Penna. RR.	266,533	243,940	1,716,111	I. 196,882
Pa. Coal Co.	107,685	160,979	942,465	I. 25,104
N. Y., L. E. & W. RR.	38,158	26,983	221,512	I. 56,849
Total.	3,324,711	2,894,702	19,951,165	I. 1,731,363

* Included in tonnage of the Philadelphia & Reading Railroad.

† This amount includes the production of the mines of the State Line & Sullivan Railroad Company, amounting to 5883 tons.

‡ In addition, there were 66,663 tons transported from the mines by the Delaware & Hudson Canal Company, during August, which is included in tonnage of other interests.

The stock of coal on hand at tide-water shipping points, August 31st, 1883, was 576,132 tons ; on July 31st, 1883, 502,159 tons ; increase, 73,973 tons.

Bituminous.

It is reported that Sydney coal is offering in this market at a low figure, and that Cumberland coal is selling cheaply at Georgetown particularly, $2.50 being the price mentioned. The bulk of the coal coming forward is of course to cover old contracts ; and though the latter were at very low prices during the early part of the season, the fact that freights have ruled low has made them more favorable to the shippers than pessimists at that time predicted.

STATISTICS OF COAL PRODUCTION.

Belvidere-Delaware Railroad Report for the week ended September 15th :

	Week.	Year. 1883.	Year 1882.
Coal for shipment at Coal Port (Trenton)	3,655	81,867	63,734
Coal for shipment at South Amboy	11,582	541,921	583,351
Coal for distribution	18,961	560,996	501,538
Coal for company's use	4,060	111,683	88,879
Total	38,248	1,296,477	1,237,502
Increase		58,975	
Decrease			

The Production of Bituminous Coal for the week ended September 8th was as follows :

Tons of 2000 lbs., unless otherwise designated.

	Week. Tons.	Year. Tons.
Cumberland Region, Md.		
Tons of 2240 lbs.	63,809	1,676,614
Barclay Region, Pa.		
Barclay RR., tons of 2240 lbs.	6,090	215,227
Broad Top Region, Pa.		
Huntingdon & Broad Top RR.	3,049	126,391
East Broad Top	384	27,394
Clearfield Region, Pa.		
Snow Shoe	2,701	158,045
Tyrone and Clearfield	54,632	1,907,427
Alleghany Region, Pa.		
Pennsylvania RR.	5,025	293,798
Pittsburg Region, Pa.		
West Penn RR.	4,213	278,192
Southwest Penn. RR.	2,476	72,918
Penn & Westmoreland gas-coal, Pa. RR	37,074	949,831
Pennsylvania RR.	14,194	400,056
Total	193,647	6,105,903

Horsford's Acid Phosphate

As a Nerve Food.

Dr. J. W. Smith, Wellington, O., says: "In impaired nervous supply, I have used it to advantage."

TYPE-WRITER COPYING.

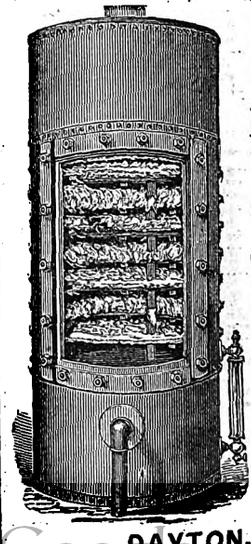
BRADLEY'S INSULATED AIR COVERING,

FOR BOILERS, STEAM PIPES, etc.

Prevents condensation of steam and radiation of heat.



SHIELDS & BROWN, 78 & 80 Lake Street, Chicago.

Send for Illustrated Circular, and name this paper.

PYRITES MINE FOR SALE.

This property is opened to a depth of 200 feet, with every thing in full working order. Machinery in excellent condition. A large amount of ore ready for stoping. The six thousand tons extracted have averaged about 45 per cent sulphur and 3 per cent copper. Immediate possession given. The mine is located in the center of the district where the greatest amount of commercial fertilizers is sold in this country. For further particulars address this paper.

STILLWELL'S PATENT LIME-EXTRACTING HEATER AND FILTER COMBINED

IS THE ONLY LIME-EXTRACTING HEATER THAT WILL

Prevent Scale in Steam BOILERS,

Removing all Impurities from the water before it enters the boiler.

Thoroughly tested; over **3000** of them in daily use.

This cut is a fac-simile of the appearance of a No. 5 Heater at work on ordinary lime-water when the door was removed after the Heater had been running two weeks.

Illustrated Catalogue.

JOHN C. TRAUTWINE, the eminent civil engineer, died in Philadelphia on the 15th inst., at the ripe old age of seventy-three, full of honors.

MR. ANDREW CARNEGIE, the great Pittsburg iron and steel manufacturer, is credited with the opinion that there is no hope for a revival of the manufacturing industries before next spring. So far as the iron and steel trade is concerned, Mr. CARNEGIE, we fear, is right. The prospects of an improvement are slight indeed, and it looks as though lower prices must prevail unless there is a further restriction of the make.

THE programme of the Troy meeting of the American Institute of Mining Engineers has just been announced. The opening session, held on Tuesday evening, October 9th, will be followed by a reception at the Troy Club. Wednesday will be spent in excursions to the stove-works of FULLER & WARREN, and to the iron and steel-mills of the Albany & Rensselaer Iron and Steel Company, there being a session in the evening. Thursday will open with a few visits to adjoining works, and there will be a morning and afternoon session, the evening being set aside for the subscription-dinner. Friday, the party will be taken to the property of the Hudson River Ore Company. The headquarters of the Institute will be at the Troy House, Mr. R. W. HUNT, President, being chairman of the local committee, and Mr. HENRY BURDEN, Secretary.

FROM Dr. HERMANN WEDDING, of Berlin, the well-known German metallurgist, comes a suggestion which may possibly be developed into a working process. While low phosphorus pig is suitable for the Bessemer and open-hearth processes, and iron carrying about 15 per cent of phosphorus is used for the basic process, the large quantities of pig which do not meet the specifications for either method of manufacture must go to the puddling-furnace. Dr. WEDDING points to the fact that, when melted cast-iron is allowed to chill, the first crystals forming are nearly pure iron, and, by repeatedly crystallizing the iron, a metal of high grade may be obtained from poor pig. The process would, therefore, be similar to that of PATTINSON in the desilverization of pig. Dr. WEDDING suggests that a battery of three open-hearth furnaces might be used for the purpose, but evidently has his misgivings as to the practicability of the scheme, which can only be tested on a large scale. We imagine that it will be difficult to impress any one with its merits to the point of putting up a plant, which can not fail to be costly.

THE autumn settlements of the prices paid for mining coal in the West have thus far passed over very peaceably, and there seems little fear of a contest between the miners and their employers. In Ohio, there will be a general advance of 10 cents per ton. In Illinois and Indiana, there has been some uncertainty, but there is reason to believe that slightly higher wages will be granted. In the railroad pits of the Pittsburg District, the winter rate has been fixed by arbitration by JOHN R. MCCUNE, the umpire of the arbitration tribunal, at 3½ cents a bushel, an advance of ¼ cent, and a compromise between the demands of the men, who asked 3¾ cents, and the views of the operators, who professed to be unable to pay more than 3¼ cents. This decision is, of course, not acceptable to the extremists of either party, but the conservative element will probably carry the day. This is, therefore, the second test of the Wallace act, and the fact that it has stood the strain of contending interests, and has avoided conflicts, is certainly an encouraging sign. We have stated our objections to it on former occasions, and as it has not been put to the supreme test which an aggravated situation would subject it to, we have no reason to change our views. It is a matter for congratulation, however, that it is giving more confidence in the efficacy of arbitration. The Wallace act may, therefore, become the forerunner of more decisive legislation.

In the river pits of the Pittsburg District, there is a disagreement in regard to the wages to be paid in the different pools. It is claimed by the operators of the third pool that, because they are paying the same price, 3½ cents per bushel, as the employers in the first and second pools, they can find a market for their coal only in the busiest season. They call attention to the fact that in the fourth pool only 3 cents are paid, and insist that in fairness to themselves and to their men they are entitled to a 3¼-cent basis.

There has been disaffection in some of the other Pennsylvania bituminous districts; but the situation being such that there is little hope for the successful issue of a strike, the men have not pushed their demands vigorously.

THE College of Mechanics of the University of California, at Berkeley, is giving evidence of a new life which promises well for the future. It has issued the first of what we trust will be a series of bulletins; and if the high standard aimed at in the one before us is maintained, the mining interests of the State, and of the country in general, may look to valuable original researches on important subjects. The bulletin before us is a modest pamphlet of fifteen pages, containing experiments with a partial turbine or tangential wheel, by Messrs. J. AHERN, E. LOUISSON, J. NEWMAN, and A. D. SCHINDLER, of the class of 1883, under the instruction of Prof. F. G. HESSE, in hydraulics, and ROSS E. BROWNE, in construction, and a number of experiments with the hurdy-gurdy wheels and a comparison of the efficiency of a Pelton wheel with that of a partial turbine, by ROSS E. BROWNE. The latter's investigation is one that is timely. He has plotted the results of a number of experiments with a hurdy-gurdy having flat and curved buckets, and with a Pelton wheel in which the amount of power lost by "carrying" the water is reduced by a special form of bucket, by the introduction of a wedge. With a flat bucket hurdy-gurdy, the best efficiency with a three-eighths inch nozzle and at 50·2-foot head was 40·4 per cent, the speed then being very nearly one half of the velocity of the water as issuing from the supply-jet. The wheel carrying curved buckets showed an efficiency of 65·6 per cent under similar conditions, though Mr. BROWNE expresses the belief that it

Digitized by Google

might have been raised 2 to 3 per cent, by attending more carefully to the curve and the size of nozzle used. The first experiments made with the Pelton wheel referred to seven different settings of the nozzle. The efficiency, when the nozzle was elevated toward the outer edge of the bucket, was 78·4 per cent, and to the inner edge 68·1 per cent. The maximum efficiency at a position approaching the former was found to be 80·5 per cent. As to the size of the nozzle, a three-eighths inch gave 82·5 per cent; a quarter-inch, 75·6 per cent; and a seven-sixteenths nozzle, 82·6 per cent efficiency, or the best result. When working the wheel with a three-eighths inch nozzle under various heads from 50 feet down to 8 feet, a gradual decrease in the useful effect was observed, although, with a head of 8 feet only, the efficiency remained as high as 73 per cent. For the best effect, the Pelton bucket should have one half the speed of the supply-jet. Mr. PELTON himself claims a higher average efficiency, and Mr. BROWNE does not dispute the claim, because the wheel he used did not precisely in all particulars conform to Mr. PELTON'S standard. So much, however, is proved, that hurdy-gurdy wheels, well designed, possess a high efficiency, under a wide range of conditions, and its best form, the Pelton wheel, shows a better effect than a partial turbine, which showed only a useful effect of 75·1 per cent as a maximum. Mr. BROWNE justly protests against the term "impact" wheel as applied to the hurdy-gurdy, which is a far better machine than it is generally given credit for.

THE tariff discussion is going on at a lively rate in Germany, and the iron trade is among the most energetically attacked industries. Compared with our own neat percentages of duty, the figures for the justification of which the German iron-masters are so earnestly writing are a mere pittance, and yet they are able to marshal an array of figures to prove how much better their workmen are doing. The Association of German Iron and Steel Manufacturers has, through its secretary, Dr. RENTSCH, gathered statements from 325 firms of producers of pig-iron, steel, and wrought-iron in all its forms, founders and machinists. In January, 1879, before the passage of the present German tariff law, these 325 firms, which included 107 incorporated companies, employed 153,979 men, to whom 9,383,396 marks of wages were paid during the month. In January, 1883, the same works had a working force of 206,150 men, the monthly pay-roll footing up to 14,754.350 marks. This shows an increase in the number of men employed of 33·9 per cent, an increase in total monthly wages of 57·2 per cent, and an improvement in the average workman's earnings per month from 60·94 marks to 71·57 marks, or 17·4 per cent.

So far as the improved returns to the employers are concerned, the following summary of the returns of 107 incorporated companies will clearly show to what extent they benefited by the mild form of protection granted the industry:

RETURNS FROM FIFTY-ONE IRON AND STEEL-WORKS.

	1879.	1882.
Capital, marks	263,654,908	266,021,678
Profits, "	5,924,157	15,113,547
Losses, "	1,289,611	1,272,211
Excess of profits over losses, marks	4,634,546	13,811,336
Excess of profits over losses, per cent	1·75	5·20
Dividends, marks	4,032,178	11,702,304

RETURNS FROM FIFTY-SIX MACHINE-WORKS.

	1879.	1882.
Capital, marks	131,169,027	130,231,512
Profits, "	4,014,327	7,315,213
Losses, "	788.206	709,370
Excess of profits over losses, marks	3,226,121	6,608,843
Excess of profits over losses, per cent	2·46	5·07
Dividends, marks	3,014,424	5,503,217

It will be noted that the manufacturers of the cruder products, the iron-mills, did relatively better than the machine-works, the former nearly trebling their returns, while the latter doubled them only. It must be remembered, however, that while the year 1879 was a very poor one, both as to prices and output, the year 1882 was fairly good and in some branches exceptionally active. Still, with due allowance for this fact, the result is certainly encouraging, and it proves that, while the profits on capital are by no means more than reasonable now, the wages of labor are very largely bettered. How far the latter point is modified by the higher cost of living due to the duty imposed on breadstuffs, we have no means of ascertaining. Candor commands that we decline to accept, save with reserve, the figures collected by the German iron-masters, and to which they point with so much pride. They exaggerate the points they are brought forward to prove. Still we believe that even the sharpest critics of the policy which they are intended to justify will concede that they prove that, by the introduction of the tariff, the workmen in German iron-mills and machine-shops have gained, and that their employers are reaping only fair profits as a return on their investment.

A PATENT-OFFICE RULING.—The Commissioner of Patents has ruled that the Patent-Office, after having adjudicated certain subject matter patentable as a design, and granted a patent therefor, can not register as a trade-mark substantially the same design, and give to another and different person the right to use it as a trade-mark.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

The Gjers Soaking-Pit at the Works of the Scranton Steel Company.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: At the request of my friend, Mr. John Gjers, of Middlesborough, England, and as marking a distinct advance in our American rail-mill practice, I take great pleasure in informing you that Mr. Gjers's soaking-pits have been in constant use at these works since September 3d. During that time, we have rolled about 80 per cent of our ingots directly from the pits, without other heating, into 120-foot flange rails, weighing mainly 67 pounds to the yard. We are at present rolling about 85 per cent and upward of our ingots directly from the pits into 120-foot rails, weighing 70 pounds to the yard. With the pits, we run one heating-furnace, most of the time days only, to work up cold ingots, etc., which may accumulate from any of the ordinary causes. We find that, with four-rail ingots, six pits are easily good for about 150 tons of rails per turn. We are informed that what we are now doing has not yet been done, as regular work, anywhere else, either in Europe or here. Respectfully yours,

W. W. SCRANTON, President.

The Alluvial Tin Mines of Banca.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: In the article of Prof. W. P. Blake, printed in your issue of September 15th, I find the following:

"According to Davies, at the alluvial tin mines of Banca, a miner, with the aid of water, removes from 350 to 530 cubic feet of earth in nine hours," etc.

Curious to compare these figures with my own experience at Banca, I was rather surprised to find the same figures, and nearly the same words, at page 12 of a little book entitled "*Banca and its Tin-Stream Works.* By P. Van Diest. Translated from the Dutch by C. le Neve Foster. With two Geological Maps. Truro: Heard & Sons. 1867."

Not knowing the address of Prof. William P. Blake, I would be much pleased to find out, through you, whether a work on Banca or on tin ores has been written by a certain Davies; and if so, where I can get it.

I would also mention that I can provide parties interested in the tin-stone deposits in the Black Hills of Dakota with complete drawings and description of the portable boring apparatus used at the islands of Banca and Billiton for determining the depth, the extent, and the value of stream-tin deposits, recommended by Prof. W. P. Blake as useful in the small valleys of the Black Hills. Respectfully, P. H. VAN DIEST.

DENVER, COLO., Sept. 20.

[The work of Davies, referred to by Professor Blake, of New Haven, Conn., is on metalliferous mining in general. We presume that Mr. Davies quoted the figures alluded to from Mr. Le Neve Foster's translation.—EDITOR ENGINEERING AND MINING JOURNAL.]

Taxation of Inventors and Use of Patent Fund.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Is not the present opportune for renewing the subject above indicated, with the object of approaching honorable members of our legislature *through their constituents?* Your readers well know that congressional attention has been yearly invited to these and kindred questions affecting the rights of intellectual property, with inadequate results. It is now evident that Congress can only be induced to give that attention to the subject which its importance justifies by personal appeal to its individual members by their constituents, supplemented by a numerously signed memorial to Congress itself. In view of the assemblage of so many of those more especially interested in such questions at the present time at the various exhibitions and conventions, and the near approach of the congressional session, it is suggested that you continue the good work, by giving publicity to a draft of memorial such as now inclosed, and by urging the personal attention of your readers.

CINCINNATI, Sept. 17. G. H. KNIGHT.

MEMORIAL.

To the Honorable the Senate and the House of Representatives of the United States in Congress assembled:

The undersigned, manufacturers, inventors, and other citizens interested in the progress of the useful arts, respectfully represent:

That to the law granting to inventors for a limited period the exclusive use of their discoveries, the country is indebted for much of its pre-eminent prosperity.

That the surplus to the credit of the patent fund (amounting on the first of July, 1883, to $2,500,000 in round numbers) remaining unappropriated to any of the ostensible purposes of its exaction constitutes a special tax upon a useful class of citizens (mostly "poor but making many rich") without constitutional sanction and neither expedient nor just.

That the fees for granting patents of invention should not (as they have done for many years past) greatly exceed the expenses incurred in examination and other procedures called for in such grants.

That the surplus could and should be applied (under proper safeguards) to means for increasing the usefulness of the Patent-Office both to inventors and the public.

That among these means are adequate digests and indexes of improvements in the various useful arts, for the use of the examining corps and of inventors and others in the principal industrial centers; increase of the working force of the Patent-Office on salaries that shall secure and retain competent service; and enlargement of its present cramped and inadequate accommodations.

Under the present law, previous grant of foreign patents operates to limit the term of one granted here for the same invention to that of the

Digitized by Google

earliest expiring foreign one, possibly because it was thought that the American public should not be called on to pay for what was free elsewhere. The provision, while oppressive to inventors of the more important improvements, fails to accomplish the ostensible object of its enactment in the great majority of American inventions; which (because of this clause) are never patented outside of the United States, and are therefore free abroad from the first. We ask the repeal of this worse than useless clause.

Legislation is asked that shall enable amendment (after due public notice and within reasonable time after grant) of a defective specification, without on the one hand bringing into subjection machines already constructed or (on the other hand) releasing previous trespasses on claims remaining unchanged in the amended specification.

It is submitted that a commission be established with authority to order such Patent-Office expenditures not in excess of receipts as such commission may (from time to time) deem fit.

It is requested further that the President be authorized to enter into arrangements with other powers for the international protection of rights of inventors; such a movement having already been made by the English government in the Patents, Designs, and Trade-Marks Act of 1883.

The Montana and Arizona Commissioners at the Denver Exhibition.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Inasmuch as some prominence has been given by the Denver daily newspapers to the attempt of the Arizona and Montana commissioners to remove their exhibits from the building of the Denver Exhibition Association, we have deemed it advisable, through the medium of your columns, to give an explanation of the reasons by which we were actuated, to the end that your many readers in those territories may fully understand the questions at issue. The commissioners of the other territories would join in this statement, were it not for the fact that they long ago foresaw the uselessness of remaining, and therefore went home. Professor Clayton, of Utah, returned two weeks after the opening; and Mr. Onderdonk, of Idaho, followed his very sensible example one week later. Nevada, the mother of silver mining, refused to send an exhibit here, as did also California. Mexico is represented by only one case of ore, and New Mexico did not show up until eight weeks after the opening. No other State or territory in the Union was represented, and only six of the counties of Colorado appointed commissioners to represent them. They are as follows: Clear Creek, Gilpin, Chaffee, Fremont, Gunnison, Summit, and Garfield. Lake County, where the greatest mining camp in the world is located, and which last year produced two thirds of the State output, refused to appoint a commissioner, and is represented only by a portion of last year's exhibit, with no one in attendance. Large additional mineral exhibits were promised by the management, but they never came. The thousands of Eastern tourists and capitalists whose coming was positively promised in the flaming and high-sounding prospectuses did not put in an appearance. Local exhibitors refused to occupy the spaces previously engaged. Machinery Hall remained a barren waste. The attendance, which for the first two weeks had been quite good, fell away to almost nothing. The mining papers of the State began ridiculing the enterprise, and the Denver *Tribune*, a fearless and outspoken journal, pronounced it a transparent fraud, a cold-blooded real estate speculation, an insult to the intelligence of the country, and a calumny on the great mineral industry of the West. The truth of these statements was evident, and an opposition and apathy were engendered which, within a month after the doors were open, virtually concealed the enterprise from public view and consigned it to the oblivion of the past. The propriety of closing the show was canvassed by the board of directors, and openly advocated by the assistant-secretary, on whose shoulders most of the burdens fell; but the probability of damage suits by the few private exhibitors resulted in the determination to keep the doors open until the close of the time specified. It was a knowledge of these facts that induced the Arizona and Montana commissioners to make a move in defense of the great territories they represent; and though they had previously uttered no complaint and exhibited a most commendable charity and patience, they determined to move, and notified the management of their intention. Then uprose the general manager, a very estimable gentleman, and vetoed the proposed movement. The matter was taken to the courts, and Judge Elliot restrained the commissioners from removing their ores, but did not restrain them from packing the same, which was accordingly done by the Arizona representative. The Montana ores had been already boxed.

Since that time, the matter has remained in *statu quo*, the management refusing to allow the removal of the ores, and the commissioners, with equal pertinacity, refusing to unbox them for the entertainment of the few women and children who visit the Exhibition. As a last desperate resort, to increase the attendance and relieve the painful solitude of the almost empty building, the management has hit upon the novel and business-like expedient of getting up a pumpkin-pie festival, as you see by the inclosed programme.

Now we respectfully submit that this whole business has been a farce and an outrage on every mining district in the West. Lured here by shameless misrepresentations, never intended to be carried out, we were compelled, in simple self-defense, to move our ores if possible to some point where their merits would be seen and understood by men of capital: and having received invitations to send our ores to Chicago, Cincinnati, and Boston, we made the attempt to leave the Denver Exhibition cemetery. The people of Colorado do not indorse it, the business men of Denver repudiate it, the mining population ridicule it, and the press, with few exceptions, denounces it. It is not a national mining exhibition in any sense, and the wisely deserted exhibit of the great territory of Utah, which will soon be removed to Salt Lake, is the only territorial exhibit in the building.

The object of this article is to give the miners of the various districts of the West a plain, unvarnished tale concerning an enterprise which is the very opposite of what it is represented to be. Respectfully,

DENVER, COLO., Sept. 20.

DOUGLAS GRAY,
Commissioner from Arizona.
JOHN B. READ,
Commissioner from Montana.

NOTES ON THE EXHIBITION AT DENVER.—IV.

Special Correspondence of the Engineering and Mining Journal.

PARK COUNTY.

The exhibit of this county is both varied and excellent, containing in some instances very rich specimens. The largest exhibit is that from the Fanny Barret mine, which occupies the center of the pavilion. This mine is situated in the Alma District, and the ore assays from 40 to 196 ounces of silver and half an ounce of gold per ton, with 50 per cent of lead. It is one of the largest mines in the county.

A number of mines from the Montgomery District have exhibits here this year, among which is the Ellen Bayne, which shows a fine block of ore. The Illinois is represented by ore containing 1·43 ounces of gold and 15 ounces of silver per ton. The Rob Roy has ore worth $250 per ton, and the Centennial shows some very good specimens, its ore averaging from 2 to 5 ounces of gold and from 5 to 30 ounces of silver per ton, in a kind of brown iron oxide. One small box contains ore estimated to yield 310 ounces of gold per ton.

The Buckskin District has perhaps the largest number of representatives, many of which show very rich specimens. The Golden Queen shows a fine specimen of ochreous ore, containing 60 ounces of silver per ton. The White Quail shows a large block of ore, containing 7½ ounces of gold and 60 ounces of silver per ton. The Earnest has ore which is said to contain from 300 to 13,000 ounces of silver per ton. The Lizzie Abington exhibits ore freely stained with carbonate of copper, worth from $100 to $130 per ton. The Parole shows some very rich ore, containing 1028 ounces of silver per ton. The Criterion has a very beautiful specimen, made up of large acicular crystals of cerussite, mixed with rich steel galena. A heap of specimens of sulphuret ores from the Red Lion mine, assaying from 500 to 1000 ounces of silver per ton, is also shown, and the Ten-Forty mine has even richer ore than this. The J. G. Blaine, also in this district, shows a curious specimen of copper glance imbedded in carbonate, the whole being disseminated through quartz rock. Among these rich exhibits, no district has a finer display of copper silver ores than Hall's Gulch and Valley. One mine, the Copper King, shows two splendid lumps of green carbonate of copper. The vein is 32 feet wide and the pay-streak 30 inches. The Missouri mine shows a large block of bismuth silver ore. But the most notable exhibits are two cases containing exhibits from the Whale mine and the properties of the Hall's Gulch Mining and Tunnel Company respectively. The former's case contains specimens of an ore which is chiefly galena, but mixed with copper glance, assaying on an average 90 ounces of silver, 25 per cent of lead, and 8 per cent of copper. The latter exhibits some very rich specimens, one being a nugget of silver and another a piece of pure silver glance. They also show a quantity of peacock ore and silver glance mixed, and some bismuth silver. The mines represented are the Great Eastern, the Manhattan, and the Kalamazoo. The Kansas City, on Democrat Mountain, shows a peculiar porphyritic-looking ore.

The Mosquito District is also well represented. The Orphan Boy shows rich gold ore, containing 12 ounces per ton, besides some silver. The London shows a piece of ore containing immense crystals of iron pyrites containing from 5 to 10 ounces of gold, from 7 to 10 ounces of silver, from 3 to 6 per cent of copper, and from 8 to 10 per cent of lead per ton. The Sunny South has a specimen showing wire silver. The Sacramento, in the district of the same name, shows a splendid block of galena assaying 1300 ounces of silver per ton. The Dunderberg (head of Platte) has ore containing 0·7 ounce of gold, 25 ounces of silver, and 73 per cent of lead per ton. There is also a specimen of ochreous carbonates from the Carbonate mine, Silver Heels District.

CHAFFEE COUNTY.

The biggest mine in this exhibit, so far as the future is concerned, is undoubtedly the celebrated Mary Murphy and its adjuncts, worked by the Murphy Company, on the Murphy spur of the Chrysolite Mountain, in Chalk Creek District. The vein is said to be traceable for miles. Several large blocks of ore associated with quartz rock, and consisting of steel galena, are shown. There are about 3000 feet of development on the mine. Last year, little ore was shipped, on account of the extortionate rates exacted by the Union Pacific Railroad. The Quincy is another mine in this district which has a 5-foot vein with 2 feet of pay ore per ton. The Mollie, which is located on the same vein as the Murphy, shows ore containing free gold and sulphurets of silver. This ore is mixed with a large quantity of silicate of manganese. An immense block of ore from the Tiger lode is shown, weighing 3700 pounds. The Tressa C. shows some fine ore. It is a copper and lead ore bearing gold and silver as follows: $136 gold, 60 ounces of silver, 9·5 per cent of copper, and 5 per cent of lead per ton. It has 200 feet of development, and was sold last week for $75,000. The Iron Chest, also on the Murphy vein, shows specimens of its ore.

In the Monarch District, which is one of the richest in the county, the following mines are noteworthy, both as to value and exhibits: The Ben Hill has galena and carbonates mixed. The vein is 6 feet wide, with pay-streak 35 inches. The Monarch, the first discovered in the district, has some splendid ore, with a most curious formation. One specimen shows it well. The piece is divided in the center by a well-marked line, the top being fine galena, and the lower portion carbonate rich in silver. The mill-runs give 1000 ounces of silver and 60 per cent of lead per ton. The Mountain Chief, in the same locality, shows ore also. The vein is four feet wide, and the pay-ore from 1 to 2 feet, carrying carbonates, galena, and sulphurets of silver. The Lost Wonder has 450 feet of development on a six-foot vein, with from 16 to 36 inches pay-ore, chiefly galena. Just below it, is a mine which produces rich molybdenite, some beautiful specimens of which are shown. The Madonna is a large mine, with ore very similar to that found at Leadville, consisting of carbonates and galena, some sand carbonates, and large masses of an ore rich in sulphate of lead. It ships from 50 to 70 tons a day; and when the railroad is completed, as it is expected it will be in a few weeks, it will send off about 100 tons a day. The Cottonwood District is well represented by specimens; but the mines have generally only a small development, and have not as yet shipped much ore, so that the assays are delusive. The Gladstone mine is an exception, as it has shipped a considerable amount of ore. Its first grade runs from 65 to 100 ounces of silver and from 18 to

Digitized by Google

27 per cent of lead; and the second grade, from 30 to 40 ounces of silver and from 7 to 14 per cent of lead per ton. The ore consists of carbonates and galena, and its development is 400 feet. The Hortense, on Mount Princeton, has also shipped a considerable quantity of $75 ore lately. Among other mines worthy of mention in this district, are the La Plata, which shows a specimen with native silver upon it; the I.X.L.; the Black Prince; and the Tilden, in Alpine District. The Black Prince is an instance of the folly of trusting to assays of small quantities. The assays gave 240 ounces and 936 ounces of silver per ton, while the mill-run gave only 73 ounces per ton. The Longfellow is a new strike of last spring. Its ores are dignified with a show-case. The bulk of the ore is carbonate and galena, the silver being in the form of chlorides.

Hinsdale and Custer counties both have excellent exhibits, but they are not labeled, and have no one in charge of them. This is a great want this year, and the counties which have refused to provide for the expenses of commissioners have pursued a very short-sighted policy.

DOLORES COUNTY.

In the center of this compartment, is a large four-sided pyramid, carrying a very interesting exhibit from the comparatively new camp of Rico, which, on no less authority than that of Senator Hill, is likely to become another Leadville. Certainly the appearance of the bulk of the ore shown reminds one of the Lake County exhibit very much. At the top of the pyramid, are some fine blocks of iron pyrites and galena, mostly from the South Park mine, a small lot being from the Nora Lilly. Lower down, are large blocks of the hard carbonates so plentiful in the Lake County exhibit; one block from the Puzzle mine being said to assay 500 ounces of silver per ton. Around the lowest two tiers, are a number of sacks full of sand carbonates and milled ore from the Puzzle, Pigeon, Parole, Leila Davis, and the Newman group worked by the Marrs Consolidated Mining Company, including the Swansea Extension, Chestnut, and Newman mines. The mines of this group turn out carbonates and sulphides chiefly. There are two upright cases which also contain many rich ores. One has many splendid blocks of ore from the Newman group. The Hope & Cross, a carbonate, assays on the mill-run 350 ounces of silver per ton, and the C. B. & Q. shows a quartz yielding from 2 to 6 ounces of gold. The Rico, also a carbonate ore, runs from 115 to 800 ounces of silver per ton. The Rico No. 2, a galena, gives from 50 to 222 ounces of silver, and the Rico Carbonate Tunnel, from 25 to 600 ounces of silver per ton. The Johnny Bull has some extraordinary ore of a dark color, and showing sulphides containing, so it is said, 280 ounces of silver and a large quantity of gold per ton. The Uncle Ned ore runs 240 ounces of silver, and the Round Up and Little Hattie, both in the Trout Lake District, show ore assaying 334 ounces and from 140 to 600 ounces of silver per ton respectively. The Bancroft has a large show of fine-looking ore running 80 ounces of silver and 40 per cent of lead. Among the others of the same class, the richest are the Little Sadie, Alleghany, Ah! Joy, Little Emma, Black Hawk, Grand View, and Golden Fleece. The Blue Cloud seems to be promising well. It shows rich copper ore containing carbonates. It is also stated that it has 1000 tons on the surface. The Sinbad exhibits a quartz assaying 3000 ounces of silver and 29 ounces of gold per ton. There is also a most beautiful specimen of large aggregations of crystals of carbonate of lead. Some specimens of coal are shown from Grand View Banks, seven miles from Rico, and therefore very convenient for the smelters; and in one corner is an immense heap of yellow carbonate ore from the Wabash mine, which has a forty-foot vein. It is stated that there are 4000 tons on the dump.

SUMMIT COUNTY.

This exhibit has many large and fine specimens representing chiefly the silver-bearing sulphides, though there are carbonates from some notable mines. The Washington mine, on Nigger Hill, eclipses all other exhibits so far as weight and size are concerned. It shows 14 tons of pure galena in immense lumps. The Snake River District is well represented by a number of rich mines. The St. John mine shows a large piece of fine ore consisting of steel galena, and showing ruby silver worth $900 a ton. The Ericsson also shows galena worth $120 a ton. The Lancaster shows gray copper and galena containing 90 ounces of silver a ton; and the Cashier, a gray copper containing $500 worth of silver per ton. The Delaware, in the Peru District, exhibits steel galena. The Decatur has a free-milling gold quartz, the metal sometimes being visible to the naked eye. The Fredonia shows a rich specimen, and the Governor (Blue River District) is represented by a fine specimen of silver-lead ore. The Gold King, from the Swan River District, shows a free-milling gold ore. One of the richest mines in the county is the Argenta, on Fletcher Mountain. There is a large and handsome case of fine ores from the mines owned by the Colorado & New Mexico Consolidated Mining and Smelting Company. The Queen of the West, in the Ten Mile District, exhibits silver ore; and there is a fine block of galena and pyrites from the famous Robinson mine. The Coley lode, Montezuma, said to be the first discovered silver vein in the State, having been located July, 1863, shows a lot of ore. The North Swan has a gold and silver ore on exhibit. There is a quantity of ore from the Brooks silver mine, Breckenridge; the Wellington mine, Blue River District, shows an immense block of very rich ore; and the Sankey Tunnel, ore containing gold, silver, and copper.

UTAH TERRITORY.

This territory has certainly a very splendid collection of ores and some remarkable curiosities. The ores are well arranged in neat cases, and, though there are not many mines represented, the exhibit leaves nothing to be desired so far as it goes. The minerals exhibited are not merely confined to those containing the precious metals. There are some excellent iron ores, some of which are smelted at Ogden; also coal, fire-brick, marbles, gypsum, salt from the Great Salt Lake, and a large collection of native sulphur ores. The beds represented are the Cave mine beds, Bradshaw, running from three inches to 12 inches in thickness, and associated with a curious porous carbonate of iron; the Morgan District bed, which shows some large pieces of rock covered with fine crystals of sulphur, as are also the specimens from the Cave Creek District, Millard County. Among the splendid exhibits of silver ore, the following are well worth mentioning: The Eureka Hill, Tintic District. The Rebellion, has a series of most beautiful specimens of blue and green carbonate of copper, besides sulphides. It is owned by the Crescent Silver Mining Company, and is located at Pifion Hill, Uintah District. Carbonate mine has a splendid exhibit of sulphides. There also some rich sulphides from the celebrated Emma mine. The Flagstaff is represented. The Cactus has a grand lot of specimens of peacock ore with 30 per cent of copper, and some gray copper ore running high in silver. The celebrated Ontario mine, with its enormous output, comes out strongly. There is also a splendid exhibit of stibnite from the mines of the American Antimony Company; and, of course, a lot of rich specimens from the Horn-Silver mine. The Barbee & Walker sends some curiosities in the shape of large specimens of petrified wood containing silver. The Comet mine shows specimens of copper pyrites. There are some large pieces of a silver-bearing sandstone rock worked by the Christy Mill and Mining Company, and some rich ore from the Old Hickory mine, consisting of copper glance and carbonate. There are also many specimens of the wonderful cerite or mineral wax, a crude form of paraffine; and some bituminous shale and oil rock. The mines for these are the Covington, Stoddart, Rose, and others. There are some curious sandstones in which the cerite appears in fossil-like forms resembling the sigillaria and stigmaria of the coal-beds. With this exhibit is a case of copper and lead ores from the Wood River District, Idaho; but there is nothing very noteworthy about it.

NEW MEXICO.

The principal counties represented in this exhibit are Grant, Santa Fé, Dona Ana, Taos, and Socorro. The ores are chiefly gold, silver, and copper, and, though they are generally inferior in appearance to the Utah exhibit, they are certainly among the richest in the exhibition. It would be an injustice to attempt to describe them in the space at my disposal, as there are at least 350 mining properties represented, some of which are well known; for instance, such mines as the Sierra Grande group in Lake Valley, and the Homestake mine, with its rich gold ore. Some grand specimens are shown from the Cañon del Agua and San Pedro mines, which work a contact vein with a 37-foot face at the surface, and which contain an 18-inch gold-bearing streak. There are also specimens of an excellent anthracite coal, mica, and a micaceous silicate from which good china can be made. Judge Sloan, the Commissioner, has also an elegant collection of his own on exhibition, representing all the different kinds of ore worked in the territory. It is much to be regretted that the Arizona exhibit should, like that from Montana, have been hidden from public view soon after it had appeared. The commissioners from these territories wished to move their exhibits to some of the Eastern exhibitions. This was declared contrary to the rules of the management, after they had once entered. The case was taken to the law courts, and it was decided that they must stay as stipulated until the close of the Exhibition; but they were not obliged to show; therefore the exhibits were packed up. It seems a pity that this action should have been taken; for, being obliged to stay, it was surely judicious to make the best of it.

In machinery, there are a few things which have not been mentioned yet. The Hendrie & Bolthoff Manufacturing Company exhibits a hoisting-engine by the Lidgerwood Manufacturing Company, and a high-speed Westinghouse engine, both in motion. Among pulverizers are two on the iron ball crushing principle, one made by S. P. M. Tasker, and the other called the Tenderfoot pulverizer, which when driven, as it requires to be, at a high speed, must wear very badly, though the work is well done. This also has another disadvantage, namely, that the ore must be crushed before it can be treated.

In conclusion, it may be said that the attendance this year has not been good at all—probably not more than half that of last year; but all who have come, especially those from a distance, have expressed their delight and astonishment. Indeed, Denver, strange to say, has been the worst enemy of the Exhibition, partly by not sufficiently patronizing it, and partly by giving it a bad name. The mineral exhibit is quite up to that of a year ago, so far as it goes, though several counties will be missed by those who read last year's report. But the space occupied by the Denver merchants last year is unfortunately very bare. This is said to be due to jealousy of the promoters of the Exhibition. Though a private concern, it is undoubtedly for the public good, and what benefits the surrounding country must surely be advantageous to Denver merchants. Indeed, there never was a clearer case of "cutting off the nose to spite the face," and it deserves the unqualified censure of the press.

Sept. 22. A. COPELAND.

PROGRESS IN THE SAN JUAN COUNTRY.

Special Correspondence of the Engineering and Mining Journal.

Since my last letter, many important developments have been made in San Juan County, and ore-shipments have increased amazingly. At present, the weekly output averages over 500 tons, and such preparations are making that there is little doubt of an equivalent production during the winter months. Competition between Denver, Pueblo, and Durango has at times been very brisk, each smelting point endeavoring to pick up the most desirable and least refractory ores. To some extent, Salt Lake City has entered the market as an ore-buyer in the northern section of the country, but as yet with but limited success, on account of the cost of transportation to the railroad at Montrose. The rivalry existing between Silverton and Ouray has given a decided impetus to mining business, which will not culminate until each town has exhausted its resources in the way of energy and enterprise. Otto Mears, with his nearly completed wagon-road and tramway from Ouray to Red Mountain, Poughkeepsie Gulch, and Mineral Point, is boldly tapping the very sources of supply at Silverton, in the very moment of her confident boasting of her own impregnable position. So it happens that our denizens have learned a noble lesson, and that they are now opening their eyes gradually to the fact of the existence of "greater things than were dreamed of in their philosophy." Nature has favored this locality, and so long as Ouray was content to idly view the scene and wait, Silverton was secure. The outlet of the Red Mountain District, Poughkeepsie Gulch, and the upper Animas country was via Silverton, and only trained engineers were aware of what art might do to overcome the obstacles in the way of shipment westward and northward. Ouray and her General Mears have outwitted us while we were apparently asleep. But this view

Digitized by Google

of the situation is not wholly just. Within the past few years, Silverton has grown and prospered less by the importation of capital and the increased output of ores than by the introduction of more competent and skillful managers of mines, who have been trained for their work. These men have taken in hand the problems before them in mining and metallurgy, and the results are due more to their knowledge of the situation than has yet dawned upon the minds of the general public. Their task has been a trying one, because performed in the face of all the combined power of envy and prejudice, but the result is here at last. Some of our best mines are still worked by men who know not the first principles of their business; but natural selection is gradually displacing these, and sending them back to the farms and groceries where they belong. This feature of progress alone is beginning to tell upon our industry in the most favorable way; and if the lesson be well heeded, we here have nothing whatever to fear from Mr. Mears or any of his laudable enterprises. In fact, his very projects, carried to a successful issue, will become the greatest boons this district could desire.

Free access to the Red Mountain District from Ouray means better facilities than we now have for reaching there from Silverton. We have the advantage in distance, the choice of two short routes with very easy grades, over which railroads can be cheaply constructed. And what is of very great importance, our means of access are practically unobstructed in the most severe winters. By the construction of an outlet via Ouray (or Montrose, rather), we shall be placed in direct communication with Salt Lake City, and our connection with Pueblo and Denver will become more intimate on account of the saving in the distance to those points. If these advantages do not immediately compensate us for the possible harm done by deflecting some of the business from Silverton, there will accrue much greater good by the stimulus thus given to our energies by reason of such losses of business. This will induce us to protect ourselves by improving our facilities, building roads and railroads, cheapening local transportation in various ways to compete with the necessarily heavy charges over this expensive route now in course of construction. Again, it will cause a great reaction in favor of Durango, and of necessity link our interests more closely with that locality and with Rico, giving us the very thing we most need, namely, vigorous competition on all sides. This very move will be the making of Durango, and now will come the event which, as engineers and metallurgists, we have been long predicting—railroad connection between Durango and Fort Wingate, thus placing the former town in an enviable position, equidistant between the best markets of the East and the Pacific slope. These prospects are but the beginning, and it is as certain as any known fact that this region is soon to be the scene of a great commercial struggle. Wise indeed will he be who rides ahead and calmly surveys the field before engaging his forces. Little things will decide most momentous questions in political economy, and only he who has mastered every detail of metallurgical practice will be a safe guide to investment in any enterprise of magnitude in any way connected with the economical raising and after-treatment of ore. The little experiments in mining and milling now under way in this section are but as drops in the bucket compared with what we shall see in the next decade, and the citizens of our little towns will give place to quite another population, whose whole business is that of mining and the reduction of ores.

Until now, the less one knew of the principles and practice of our profession, the better was he qualified to succeed in the accumulation of money from the handling of mines in this region. From this on, the more thoroughly one has mastered the details of the mining engineer's calling, the more will he be appreciated here and the more successful will he be in acquiring fortune in the legitimate work of his profession. Within the past few years, hundreds of worthy young men have applied to me for advice as to a field for the exercise of their talent and training while gaining a familiarity with the practical part of their calling. Such men would have been invaluable in the development of our resources, if not given too much responsibility until they had proved of what stuff they were made; but I felt compelled to take counsel from the experience of the very few really competent engineers in this section, and to advise all applicants to choose more mature fields for their early career. Now I do not hesitate to urge young aspirants who have been well trained to come this way, if they can afford a few months of unremunerative employment; for the time has come when the application of economic principles is necessitated by the competition which has reached us. And more than ever before does this region stand in need of competent surveyors, skilled chemists, and capable engineers, who will show the people the real necessity of accurate work in these departments. We are practically over the period of the rule of the mining shark, and even the most unreliable local newspapers, which have not gone beyond the stage of windy puffs and wordy head-lines, vainly used to conceal the editor's ignorance, are now obliged to condemn their own methods in their editorial columns. Here, it is a source of pleasure to be able to point to one honest effort to build up a journal without resort to this reprehensible practice of exaggerating every new discovery and reporting each prospect-hole in terms beyond the power of the best mine on earth to fulfill. I refer to the employment of a competent mining editor upon the staff of the *La Plata Miner*, published weekly at Silverton. The principle is a good one, and if Mr. Ingersoll does not perform the duty as it should be, it will be very easy to put the blame just where it belongs, and the credit of his good work will be given to the one who deserves it. In two or three years, such a paper will have a recognized place throughout the country as a truthful exponent of the resources of this district, while other sheets which adopt a different plan will be valued only by those who thrive by sales based on wild statements of ignorant and irresponsible parties; and the day for such transactions is past, never to return, let us hope. There is full enough of glory to be got out of a bald statement of actual facts, so far as San Juan County is concerned, without need of resorting to fabulous reports which these same facts do not warrant. Nay more, it is true that some of these very statements, made through ignorance of vein structure and metallurgical principles, have, to my certain knowledge, actually prevented the sale of really good properties to those whose investment here would have been of untold value to our district.

As some compensation for this long letter, I promise to send you soon a series of the bald statements above referred to, which will be well worthy of the careful perusal of intending investors. San Juan County now has no need of Denver Exhibitions or newspaper head-lines to proclaim her prowess; for is it not written in indelible characters in the statistics of production, which already place her high in the list of the mineral counties of Colorado?

THEODORE B. COMSTOCK.

SILVERTON, COLO., Sept. 17.

"COLONEL PAINE AND HIS GRIP."

The following neat poem appeared in the New York *Times* of September 24th. It is worth reading, although we are sure it does injustice to an eminent engineer:

Colonel Paine was an engineer,
Only one such, far or near.

Knitting his brows with look intense,
He swore, by the god of experiments,

The public might foot it to and fro,
The bridge might lie in a sheet of snow,

The press might howl and the people swear
From now to the crisp December air;

But as for him, he would ne'er let slip
A chance to experiment on his grip.

For the Colonel had planned a wonderful thing,
With a wasp-like body and wheel-like wing,

With a crank, and angle, and elbow, and joint,
And a pulley, and wheel at every point,

With a sidelong motion and downward swoop
And an awful and terrible backward scoop,

And all the fevered and wild ideas
That came in seventeen weary years,

Until at last his grip is able
To do all things—save clutch the cable.

But the Colonel is not downcast with fears;
He will labor for seventeen other years.

So, day by day, as the months go by,
And the people's hard-earned dollars fly,

Two things, of the fleeting world, remain,
The grip, and the gripper, Colonel Paine.

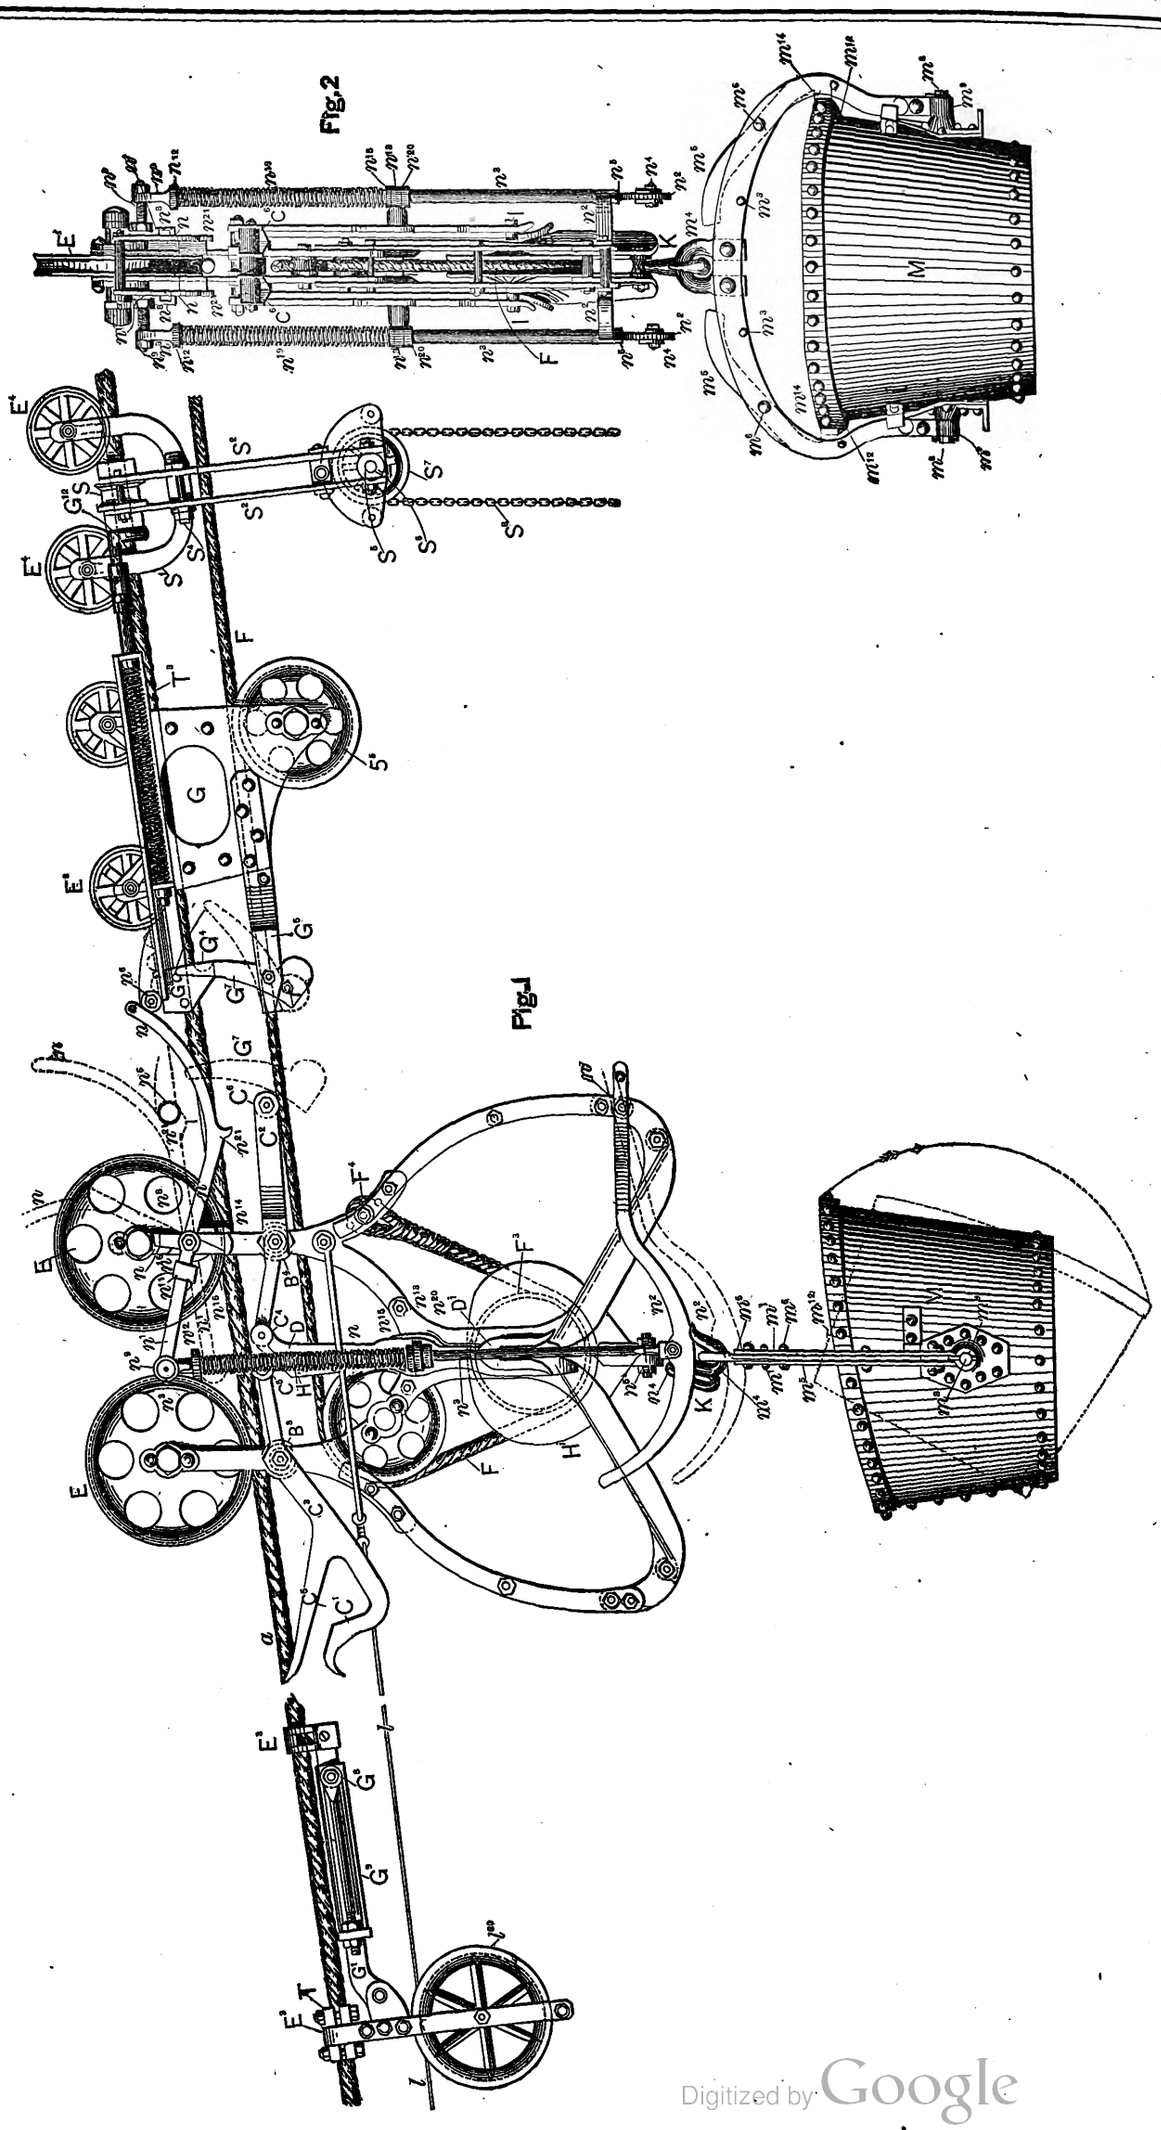
At each new hitch in its parts internal,
The blame he lays on some hot journal;

'Tis the wires, the engine, the rails, the brakes,
All being tried to avoid mistakes.

And æons hence, when the trumpet sounds,
And the dead men answer the silent rounds,

The angel will pause, as once again
Is called the name of Colonel Paine,

To hear response from a hopeful lip:
"Here! Experimenting with my grip."



PONS ASINORUM.

INTERESTING PROPERTIES OF METALLIC SALTS.

At a meeting of the Physical Society of London, Prof. J. H. Gladstone performed an experiment, showing the crystallization of a metal upon itself from a fused salt. In the course of some investigations into metallic replacements, he observed that some sheet silver placed in fused chloride of silver became quickly studded with crystals of the metal. The displacement of a metal by itself seemed so anomalous that he at first supposed the silver employed to contain impurities; but such was not the case: and he further found that iodide of silver could be substituted for the chloride with a like result. Moreover, when copper was immersed in fused cupreous chloride, zinc in melted zinc chloride, or iron in fused ferreous chloride, crystals of each of the several metals separated out. That this remarkable phenomenon was not due to different physical condition of the rolled metals was proved by putting crystals of the pure metal, separated by electrolysis, instead of the rolled metal, when fresh crystals were formed as before.

Subsequent experiments went to prove that the effect is really due to an electric current set up in the cell by the unequal heating of different parts of the metal plunged in the salt. This contact current was proved to exist by means of a galvanometer, and the two following experiments intensified the electrolysis. Some silver chloride was fused in a hard glass tube, and a rod of silver placed in it. On heating the under side of the lower end for ten minutes, a considerable crop of silver crystals was found in the cooler part of the liquid. Again: some silver chloride was fused in a crucible, and one side more strongly heated than the other. Two rods of silver were connected, one in the hotter, and the other in the colder, part of the salt. At the end of fifteen minutes, the latter was found studded with crystals, while the former was clean. Copper wires immersed in cupreous chloride gave a similar result.

THE BROWN HOISTING AND CONVEYING MACHINE.

Digitized by Google

THE BROWN HOISTING AND CONVEYING MACHINE.

During the visit of the American Society of Mechanical Engineers to Cleveland, they had occasion to inspect the working of an improved method of handling material at the ore-docks in that city. The apparatus there used was employed in hoisting iron ore from ships, and conveying it to the dumping ground on the docks. It worked with such precision and such speed that, although the party was fatigued after a day's hard work, it excited a good deal of interest and was commented on most favorably. We are pleased to be able now to give the necessary illustrations which place us in a position to describe in detail the working of the Brown hoisting and conveying machine, the invention of Mr. Alexander E. Brown, of Cleveland. A model on quite a large scale was also shown at the Chicago Exhibition of Railroad Appliances.

In his own language, Mr. Brown has set out to design machinery that will fill the following requirements: The machine must be adapted to be applied to and perform successfully all the operations required of it while supported upon any one of the cheap forms of tramway, such, for instance, as a suspended wire cable or rail track. It must perform its functions by means of motive power derived from a source located at a greater or less distance from the machine, and beyond its limits of travel, and at the same time effect the transference of the load to its place of final deposit with the least possible changes in the direction of motion of the motor. It must be capable of hoisting, carrying the load to some distant locality, and either discharging or first lowering and then dumping the material, being all the time under the perfect control of the operator. It must be strong and simple, avoid the use of spring-bumpers to take up the momentum of a suddenly shifted load, and its action must be positive and automatic. The trials witnessed at Cleveland confirm the impression which a perusal of the description of the working of the machine will convey to an engineer.

In Figs. 1 and 2 we show all the essential parts of the machine, and further details are accessible to those interested in minutiæ of

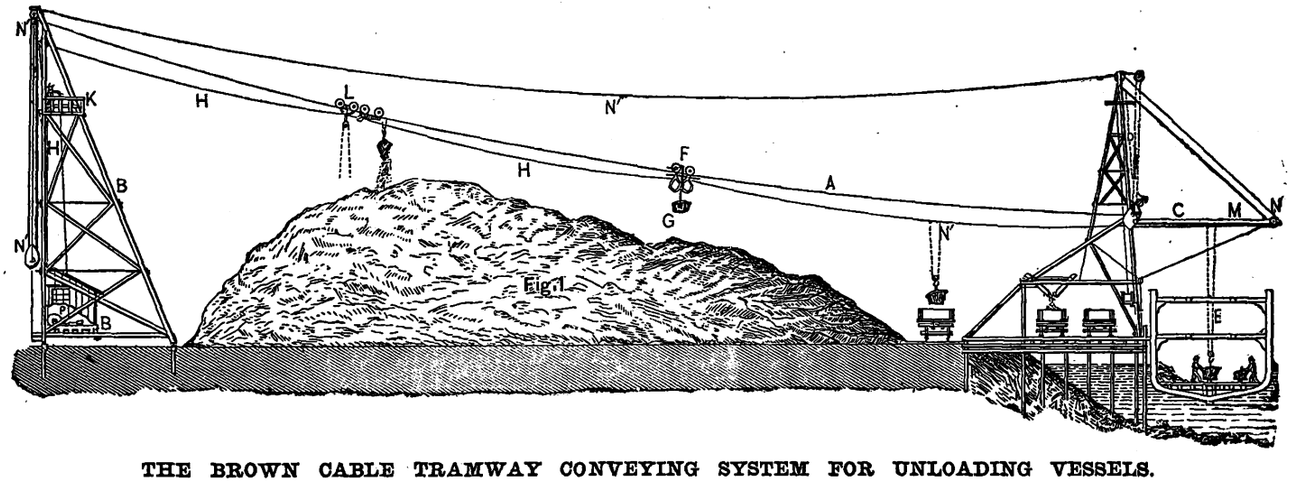

Fig. 1.

THE BROWN CABLE TRAMWAY CONVEYING SYSTEM FOR UNLOADING VESSELS.

design and construction in the very full and elaborate patents granted to Mr. A. E. Brown, No. 232,236, September 14th, 1880; No. 281,446, July 17th, 1883; and No. 281,011, July 10th, 1883. In Fig. 1, F is the hoisting-rope, one end of which is attached to a projecting portion of the carriage-frame F^4. The carriage-frame C B is provided with traveling sheaves E E running on the cableway a. The hoisting rope is wound around the sheave F^2 of the hoisting-block and over a sheave F^1 journaled in the carriage-frame, and thence over the sheave F to the hoisting-engine. Turning first to the mechanism for automatically hoisting and lowering the load at both ends of the route, it will be noted that there is attached to each part of the carriage-frame, bearing the two sheaves E E, two levers, the one to the left C^1 C^5 C^3 turning on the pin B^3, and the other C^2 C^4 on the pin B^4. Between them they grasp the upper end of a lever H (hidden in the drawing), which terminates at its lower end in a hook, which, in the position of C^1 C^3 and C^2 C^4 in the drawing, catches under the pin I (Fig. 2), passing through the hoisting-sheave, and holding it. The upper end of the lever hook H, which turns on a pin near its center, has the form ⌐. A depression of the points C^5 C^4 causes C^5 to strike the incline, and moves the upper part of the lever to the right, and disengages its lower hook end. The points C^5 and C^4 are connected also by a part D, which is provided with a downwardly-extended portion D^1, shown in the engraving, bifurcated at its lower end to straddle the pin I, and which thus serves to laterally retain that pin in the proper position. This part D^1 is also slotted near its middle, in order to allow it to pass freely by the pin around which the hook lever turns.

In raising the load, the pin I passing through the hoisting-sheave is guided by the bifurcations of D^1 against it until it strikes the upper end of the bifurcation, and by moving upward the part to which the bifurcation is attached, raises the points C^5 and C^4, and thus forces back the hook-lever H to the point where it will catch behind the pin I and thus hold the load.

The whole lever system is actuated at either end of the route by the stops G and G^1, the former being the up-grade and the latter the down-grade stop-frame. At the end of the stop-frame G, which runs on sheaves E^3, is pivoted a lever G^7, the normal position of which, by its gravity, is nearly vertical, and the extent of the oscillation of which is limited by the stop G^8. The longer area of this lever forms an inclined plane, up which the roller C^6 of the part C^3 has to ride as the carriage-frame approaches its uppermost destination, and which serves to effect the proper manipulation of the part C^2 to operate the hoist-block releasing devices. G^4 is a hook-like projection which catches the carriage should it tend to start down grade before the hook has taken hold of the bucket. In order to be able to secure the stop-frame G at any point of the cable a, a clamp mechanism is provided, connected with it by means of a buffer arrangement T^8 to take up any jar in stopping the carriage-frame. The clamping apparatus is worked by a chain S^9 and wheel.

The stop-frame G^1 is somewhat differently constructed. The inclined portion C^5 of the carriage lever system rides on the roller G^8, and is forced upward, the end C^1 meanwhile being carried up in the rear of the roller. It is designed to prevent any backing up of the carriage up grade when the weight of the hoist-block and load comes on to the hoist-rope.

Such are the devices for releasing and taking hold of the empty or loaded bucket at the stations marked by clamping on of the stops at any part of the tramway cable. The arrangements for automatic dumping are as follows:

The projecting lever n, suitably bent or curved at one end, as shown, is pivoted to the frame of the machine by a pin or bolt n^8, and is connected at its other end by means of projecting portion n^{16} of the lever n and the adjustable collar n^{11} to the lever-arm n^1, which latter is also pivoted at n^8. The lever n^1, at its other end, is in pivotal connection, by means of pin n^9, with rod n^3, which rod passes through the stationary slotted guide-nut n^{13}. The lower end of rod n^3 is connected to a lever n^2, by means of pin n^4 and adjustable screw-bolt n^5. This lever n^2 is pivoted to the machine-frame at the point n^7; n^{12} is a collar fastened to the connecting-rod n^3.

n^{19} is a suitable spring on guide-rod n^3, arranged to butt against the collar n^{12} and washer n^{15}, so as to counteract the tendency of the parts n^3 n^2, etc., to drop by their own weight from the positions shown in the full lines to that shown in the dotted lines, and which spring also serves to return the parts n^3 n^2, etc., to their normal positions after the load is dumped and the carriage is on its return down grade. n^{14} is a projecting lug from the carriage-frame, to prevent the lever n and its connecting parts from dropping lower than shown in drawings. n^{20} is a collar on the connecting-rod n^3, that serves to check undue rising of the rod n^3 and levers n^1 and n^2. n^6 is a roller or rollers suitably constructed and applied on the upgrade-stop G.

It will be seen from Fig. 1 that all those parts described are in duplicate or in pairs—one part on each side of the machine—for the evident purpose of balancing the machine or making the same symmetrical with respect to the cable tramway on which it travels. M is a tub or bucket suspended from the machine by the hook K of hoist-block F, which enters the eye or loop m^4, riveted to the bail m^1, the latter being secured to the bucket by trunnions m^9 in eyes m^9, riveted to the bail.

m^5, Fig. 2, are catch-levers pivoted to the bail, on each side of its center or middle, by the bolts or rivets m^6, Fig. 2. The catch-levers m^5 are so shaped and pivoted that when free to act by gravity or a spring the upper portions of them project some distance above the edge of the bucket-bail, as shown in the engraving, while the head m^{14}, formed on the lower portion, will project inside of the bail and in front of the stop-lug m^{12}, thus locking the bucket in carrying position. The tendency of the lower portion of the catch-levers m^{14}, either by gravity or a spring, is to drop or close, so as to lock the bucket in the position shown in Figs. 1 and 2. The shape of the bucket M is such that when fully loaded it has a tendency to turn on its pivots m^6 and dump in the direction shown by the arrow in Fig. 1. This is prevented when the catch-levers m^5 are in their normal positions—that is, with their heads m^{14} in front of the lugs m^{12}, preferably riveted to the bucket. It will be seen from this that if the upper portion of m^5 be pushed down, the bucket, if loaded, will be free to dump, as in that position the head m^{14} of the catch-lever is out of contact with the lugs m^{12}. The bucket is so hung on the trunnions that when it is empty the weight of the bottom of the bucket is such as to cause it to right itself; and when the bucket is full, the tendency of the load is to tip it over and dump the load. The bail m^1 is constructed of two pieces of iron separated from each other a suitable distance, to allow the eye of the trunnions m^9 being riveted between them. This construction also allows the catch-levers m^5 to be pivoted between the two riveted bail-pieces, thus holding the catch-levers m^5 in position and protecting them nearly their entire lengths (excepting the projecting portion of the upper end of catch-lever). The catch-levers m^5 may be made either to act by gravity by making the lower portion or head m^{14} heavier than the portion above its pivot, and thus always secure a tendency of the same to drop into locked positions with respect to the buckets. An equivalent action may be produced, without making the head m^{14} heavier than the upper part, by means of a spring or springs,

Digitized by Google

secured by rivets to the bail, and bearing against the under side of the catch-lever.

From the foregoing, it will be plainly seen that the action of the bucket and catch-levers will be such that, whenever the upper portions of the catch-levers m^5 are pushed down, the lower portions or heads of the catch-levers will be out of locking position with the bucket, and the same will be free to dump.

It will be further seen that if the levers n^2 of the dumping device, which, when not in action, always stand directly over the upper portion of the levers m^5, are pushed down, they will depress the upper portions and elevate or unlock the lower portions of the catch-levers, and dump the load contained in the bucket.

Having decided the relative arrangement of the hoisting and lowering and dumping devices, and the general construction of the various parts composing the same, we shall now proceed to describe their operation in detail.

Assuming the bucket to be loaded and suspended from the machine, as shown at Figs. 1 and 2, and pulled along by means of the hoist-rope to a position on the cable in respect to the upgrade-stop as shown, the projecting end of the lever n comes in contact with the rollers n^6 on upgrade-stop. Through the further pull of the hoist-rope, the lever n moves upon the roller n^6, and, turning on the pivot n^8, pushes down the connecting-rods n^3 by reason of their pivotal connection at n^9 with the same, which in turn forces down the levers n^2, bringing them in contact with the projecting portions of the catch-levers m^5 of the bucket, and pushing them down and the lower end up and out of locking position, when the bucket by its load freely dumps. The levers n are prevented from rolling upon n^6 farther than the required distance to open the catch-levers m^5 of bucket by means of the projecting lug n^{21}, which comes in solid contact with the roller n^6, as shown by dotted lines. This also serves as a stop or abutment for the machine, and prevents the lever C^2 of the machine from coming in contact with the swinging piece G^7, and thereby preventing the opening of the hooks that suspend the hoist-block and the lowering of the load. On the return motion of the carriage down grade, after the load is dumped, the springs n^{19} lift the levers n^1 and n^2 to their former positions, and as the lever n rolls down and off, the upgrade-stop roller n^6 and the levers n^2 are raised; the bucket catch-levers are again left free to lock the bucket as soon as it rights itself.

In practice, it is found that it is not necessary always to clamp the upgrade-stop tightly when it is desired to use the automatic dumping-device; and in fact, it is ofttimes better to leave this stop loose on the cable tramway, and only held in position by a tail-rope from running down grade. The weight or the tendency of the stop G to move down grade is sufficient to work the automatic dumping device, so that, as soon as the dumping-levers n come in contact with the upgrade-stop, the load will be dumped before it comes in solid contact against the lugs n^{21}, and when the latter do come in contact with the rollers n^6 of the upgrade-stop, the motion of the carriage is communicated to the stop itself until the carriage is returned in the reverse direction down grade. This allows considerable leeway in the operating of this dumping mechanism, as it relieves the same from any severe or sudden shocks that might be produced if the dumping-levers were brought into forcible contact with the upgrade-stop clamped to the cable. If it is desired to lower the load without dumping it—or, in other words, if it is desired to throw the dumping attachment out of operative condition—it is only necessary to slip the collar n^{11} along lever n^1 off from n^{16}, or the prolonged end of n. In this position of the collar detached from n^{16}, the lever n is free to turn on the pivot n^8, independently of n^1, to the highest dotted-line position shown in the drawings, up against the projecting hub of the carriage-wheel E^1. This will bring the other projecting end n^{10} of lever n (located about at right angles thereto) in line with n^1, when the collar n^{11} may be slid over the same, and so hold the lever n in this upright position. In this position of the lever n, it will readily be seen that the whole of the dumping attachment is out of operative position, as the lever n can not now come in contact with the upgrade-stop. It will further be seen that in this position of the dumping device, the lever c^2, that operates in opening the load-suspending hooks of the machine, is free to engage with or roll upon levers G^1 of the upgrade-stop, and thereby release the load without dumping.

The general arrangement of a plant for the use of a Brown hoisting and conveying machine is shown in the accompanying engraving. The steel wire rope A is secured by a tightening screw and ball and socket arrangement to the top of the back pier B and at the lower front pier by an apron C, which is so hinged to the front pier D that it may be lowered over the vessel E to carry the cable railway across the center of the vessel's hatch. By this method, the machine F can run out on the tramway over the hatch and lower the tubs G, holding one ton, in and out of the vessel. The hoist-rope H of the machine passes over a sheave on the back pier B to the drum of a hoisting-engine P, which is separated by means of levers on the platform K. N^1 N^1 is a counterweight and sheave-block with small wire rope so arranged and connected to the machine as to render it capable of returning light to the vessel at a speed of from 20 to 35 feet per second. This counterweight arrangement, which Mr. A. E. Brown has patented, overcomes the difficulty caused by the sag of the rope at the lower end. Both front and back piers are movable along the line of the docks on large wheels worked by gears.

The New York, Pennsylvania & Ohio Railroad Company has already stocked 60,000 tons of iron ore on its Cleveland docks, with the wire rope tramway apparatus shown, which it is claimed is three times as much as could have been stocked in any other way. One hundred thousand tons may be piled in one vessel length, the span of the tramway being from 360 to 375 feet. A second plant is finishing for the same parties, this, however, being of the trestle bridge type, a truss taking the place of the wire cable. These bridge trusses have 180 feet span each. The Brown Hoisting and Conveying Machine Company has also a cable system in use in France at Varangéville, of 350-foot span, used for unloading canal-boats and stocking coal in a yard. They are also building a shed tramway for Coxe Brothers & Co., at their transfer agency at Milwaukee, for storing and handling Cross Creek anthracite from vessels and in cars. The building will be 400 feet deep and 150 feet wide, and 50 feet high, and three tramways will have together a capacity for handling over 1000 tons of coal per day. For mining purposes, the machine is particularly adapted over open pits or for stripping or quarry work.

THE PRODUCTION AND MOVEMENT OF TIN ORES AND TIN.

Written for the Engineering and Mining Journal by William P. Blake, F.G.S., New Haven.

The apparatus for prospecting the deposits in use by the Chinese miners of Banca is described in the Report of Commissioner Hague on the Mining Industries as represented at Paris in 1878, from data furnished by Mr. De Groot. This information was drawn in part probably from an article by Van Diest in the *Berg- und Hüttenmännische Zeitung*, where probably more details respecting the construction of the apparatus can be found, as well as other interesting data on the tin deposits of the Dutch colonies.

STATISTICS OF TIN PRODUCTION.

The Mineral Statistics of the United Kingdom contain full details respecting the production in England, and also some valuable data respecting the supply of tin from the chief centers of production in other parts of the world. The following figures are drawn chiefly from that source, and show approximately the aggregate annual production and general movement of tin.

The East Indies have long been celebrated for the quantity and fine quality of the tin exported from there. Banca furnished the chief supply, in addition to the product of Cornwall, until the discovery of the mines of the island of Billiton in 1851, followed, in 1873, by the development of the tin deposits of Australia.

Banca tin is sent to Holland in slabs which average about 64 pounds in weight, 1000 weighing about 32 tons. This tin is sold by the Dutch Trading Company. In 1881, the sales amounted to 135,592 slabs, at prices ranging from 53 to 64 florins per kilo. In the same year, 78,000 piculs of Billiton tin were sold in Batavia at prices ranging from 60·33 to 75·42 per picul. The following figures give an idea of the production of tin at the tin regions and the exportation from them:

	Tons.
Banca sales in 1881	4,339
Billiton	4,735
Straits shipments to London	5,795
" " to the United States	5,680
Exports from Penang and Singapore	11,475
Exports from Sydney, Melbourne, and other ports	9,000

The production of tin ore in the United Kingdom in the year 1881 amounted to 12,898 tons 300 pounds, valued at £697,444 5s. 3d., yielding 8615 tons of metallic tin, worth £839,680. This was produced in Cornwall and Devonshire, from a total of 95 mines or workings on veins, in streams, rivers, and foreshores.

In the year 1881, there were 396 tin-plate works in the United Kingdom, of which 298 were working, and produced, by estimate, over six millions of boxes of tin, terne, and black plates. The average weight of a box of plates is 3 quarters 16 pounds, and the total weight, based on the estimate, is 280,988 tons of iron.

For the year 1881, the price of tin in the London market fluctuated between £90, the lowest, and £115 per ton, or a mean average price of £97 9s. 3d. per ton for the English block tin. The prices for the imported tin range somewhat lower. The Australian and Straits tin averaged £92 15s. 6d. per ton.

The average prices of tin ore and metallic or common block tin in Great Britain, for a series of years, are shown by the following:

Year.	Tin ore. £ s. d.	Metallic tin. £ s. d.
1876	43 18 0	79 10 2
1877	40 10 0	73 3 6
1878	35 5 6	65 12 3
1879	40 0 0	72 6 0
1880	49 0 0	91 5 0
1881	54 0 0	97 9 3

The yield of tin ("white tin") from the black tin as dressed and smelted in Cornwall, in 1877, was about 70 per cent. This, of course, depends upon the extent to which the impurities are removed by the washing or dressing process. In the Mining Records of 1853, Mr. Robert Hunt gave the average produce as about 65 per cent. In the mineral statistics of Great Britain, the metallic contents of imported black tin ore are taken at 64 and 65 per cent, and even as high as 70 per cent. The following shows the average for the years named:

1860	64	1870	67
1865	64	1875	66½

In making an approximate estimate of the total production of tin in the world, the best figures attainable are those collected at the last great Paris Exhibition in 1878, by Commissionet Hague, who was also a member of the international jury for Class 43, including ores and metals. The following table is compiled chiefly from his report, and shows approximately the world's production of tin annually at the period preceding the Exhibition, or for parts of 1876 and of 1877, and aggregates, it will be seen, over 28,000 tons.

WORLD'S PRODUCTION OF TIN 1876-1877 (APPROXIMATE).

Country.	Tons of tin.
England	9,500
New South Wales	6,505
Queensland	2,800
Victoria	60
Banca } Billiton }	6,600
France	1,000
Austria and Hungary	207
Saxony and Bohemia	200
Russia	10
Peru and Bolivia	1,500
Tons	28,382

Messrs. Crookes and Röhrig, in their Treatise on Metallurgy, com-

Digitized by Google

sidered the world's product of tin, about the year 1868, to be approximately 16,430 tons, distributed as follows:

	Tons.
Great Britain	7,200
Southern Asia and East India	7,500
Bolivia and Peru	1,500
Saxony	130
Bohemia	60
Spain	40
	16,430

But these figures are far below those reported, but from sources not stated, in the Government Report on Mineral Resources, prepared under the direction of Albert Williams, Jr., for the United States Geological Survey, which figures are as follows:

Year.	Tons.	Year.	Tons.
1878	35,597	1880	36,294
1879	37,539	1881	38,123

We know very little of the production of tin in the interior of China and in Central Asia. It is well known, however, that there is an important tin-bearing district up the Yellow River in a granitic region. The principal localities are those of Laos and Yan, described or noticed in a report to the French Government by Fuchs and Saladin, and translated by Charles Smith, Inst. Civil Engineers, London. See also *Annales des Mines*, 1882, ii., 185–298. At Yan, it is said that tin and salt are bartered evenly, weight for weight. In consequence of the "Black Flags," the quantity of tin now annually brought to Ha Noi is only 1000 tons, instead of from 3000 to 4000 tons, as before the year 1874.

A large quantity of tin in slabs or pigs is imported annually by Japan, but no statistics are accessible.

IMPORTS OF TIN—UNITED STATES.

The United States import annually from five to six millions of dollars' worth of tin in bars or pigs, and from sixteen to eighteen millions of dollars' worth of tin plate and manufactures of tin, as shown by the statistical tables of the United States Bureau of Statistics, Treasury Department, Washington, from which the following figures are drawn:

IMPORTS OF BAR TIN.

Year.	Pounds.	Value.
1882	18,661,600	$4,953,538
1883	23,781,400	6,106,250

MANUFACTURES OF TIN.

Year.	Pounds.	Value.
1882	393,686,900	$16,599,264
1883	432,177,400	17,699,239

The years indicated are the fiscal years ended June 30th.

COAL-CUTTERS IN THE PAN-HANDLE FIELD.—Mr. Robbins, the well-known operator of the Pan-Handle field, is busy preparing for the most extensive application of machinery to coal-digging that has yet taken place in this vicinity. His tract, recently purchased near McDonald station, embraces 400 acres of untouched coal. He is placing air-compressors in position for furnishing the motive power to Lechner and Harrison coal-digging machines, which will be used exclusively. Mr. Robbins and W. P. Rend are the owners of the right to use these diggers in the regio n named, and the latter's success with them induced Mr. Robbins to engage in their use on a bigger scale. The Lechner machine "bears in" by operating cutting knives, while the Harrison machine operates a reciprocating drill. Both machines are to be run day and night when preliminary operations are finished. One of the oldest Pan-Handle operators in the tract estimates the advantage Mr. Robbins will have through the use of mechanical diggers, over other operators, as at least 50 cents a ton in open market. He also stated that the causes operating against the general use of the machines were threefold, the objections of the miners, the first cost of the air-compressing and other machinery, and the unfitness of pits opened in the usual way for occupancy by the machines. This last objection will be done away with in the present instance.

FORT COLLINS, COLO., AS A RAILROAD CENTER.—A correspondent of the Denver *Tribune* writes as follows from Fort Collins: There have been railroad rumors of every description floating around of late, and many of them have the appearance of reliability. This has long been the coveted spot of several railroad corporations, from the fact that the Union Pacific does more business here than at any other point in Colorado, possibly barring Denver. This company can utilize all its East-bound freight cars, which are sent back to the East empty on some of the roads, by hauling grain, vegetables, and produce, but more especially stone. This article is taken out in great quantities at the quarries just west of the city, and finds an excellent market, principally in Omaha, Lincoln, Kansas City, and St. Louis. The stone is used for both paving and building, for both being superior to any stone in the Western country. The paving and curbstone is the finest that can be obtained in any locality. Thus the Union Pacific can take back to the East trains loaded with stone and with produce, while the other roads have to take their freight trains back mostly empty. For this reason, several of the different roads have cast a longing look in this direction, and have had surveyors in the field locating and running lines to Fort Collins, and over into the great mineral fields of North and Middle Park.

It is understood that the Burlington & Missouri has been trying to purchase several stone quarries east of this city, of parties, and that the sale will be consummated in the near future. This looks very probable, for numerous reasons. First, the company wants necessarily a large amount of stone for bridges and railroad work; secondly, it would then be able to run as heavily-loaded freight trains East as West; thirdly, there is an immense amount of grain, hay, flour, and produce of all descriptions shipped from this section to outside points. The company has had surveyors in the field who have located lines with good grades, up through the Poudre Cañon, and another by the way of Long Pine Creek over into the great mineral fields of North and Middle parks, and finally out on the Pacific slope.

FURNACE, MILL, AND FACTORY.

The Chicago Rawhi de Manufacturing Company received an order on the 17th inst. for 4400 feet of its rawhide belting, to go to Sydney, New South Wales.

The Lechner Machine Company, Columbus, O., has recently shipped ten of its coal cutting machines to Alabama, for use in the Pratt mines, near Birmingham. The company has removed to its new quarters, where, with better facilities and plenty of room, it is better prepared to attend to its growing trade for the Lechner mining-machines and also the company's patent detachable chain-roller belting, which is gaining a good reputation and is extensively used at mines, mills, and reduction-works. The following are some of the many companies now using them: The Columbus & Hocking Coal and Iron Company, at six of its Hocking Valley mines; the Upson Coal Company, Shawnee, O.; the Ohio Central Coal Company, Corning, O.; the Nelsonville Coal and Coke Company, Nelsonville, O.; W. P. Rend & Co., McDonald's, Pa.; the Witch Hazel Coal Company, Youngstown, O.; the Illinois Central Coal Company, St. John's, Ill.; the Boston & Colorado Smelting Company, Argo, Colo.; and the Millen Mining Company, Coppersville, N. H.

The new machine-shops of Messrs. H. N. Nichols & Co., Denver, Colo., are quite completed. The machinery will be in place and every thing be ready to move in a couple of weeks.

It is probable that the Roane Iron Company will equip a mill for the manufacturing of nails. A good many near-by enterprises are talked of, and some are under way. Kenton, Tenn., is to have a steam flour-mill. Sparta, Tenn., a planing-mill. Mayville is to have a woolen-goods mill. The Tennessee Coal, Iron, and Railroad Company, at South Pittsburg, will build 200 additional coke-ovens. The Dade Coal Mining Company, at Elberton, Ga., is enlarging its facilities for mining. The Central Iron-Works, of Helena, Ala., are changing rolling-mill machinery, and replacing it with machinery to manufacture rails.

Monocacy Furnace, in Berks County, Pa., has been repaired and was to go into blast this week.

Vulcan Furnace, at Newberry, Mich., has gone out of blast, and will be overhauled and repaired.

Eliza Furnace, in Jackson County, O., has been rebuilt, and will go into blast in about two weeks.

Milton Furnace, in Jackson County, O., is undergoing repairs and improvements, and will go into blast as soon as it can be made ready.

The Colorado Iron-Works, Denver, Colo., recently shipped a ten-stamp mill to McKitrick & Co., Gold Park, Holy Cross District; also roasting-cylinder with rolls, concentrator plant, etc., to the Kate Mining Company, Saguache County.

The Colorado Machinery Company, of Denver, Colo., reports the sale of a 40-ton water-jacket smelter complete, to go to Ogden; also a 1¼-mile Houson wire rope tramway for a mine near Silverton, and a Houson tramway for the Belden mine, Red Cliff.

The French Spiral Spring Company, which is building a large mill between Twenty-fifth and Twenty-sixth streets, below Penn avenue, Pittsburg, is drilling a well for gas. This will be one of the largest spiral spring works in this country, and will be provided with the most improved machinery.

Messrs. Hendey & Meyer, Denver, Colo., have just received an order for a mammoth engine to be shipped to Kansas City. They have also made one of their automatic cut-off engines, 110 horse-power, for the American smelters, at Leadville, also another for Durango in Mexico.

The Linn Iron-Works, at Birmingham, Ala., have just completed an enormous plate shears. It weighs 40 tons, and has two knives 75 inches long, which will cut a sheet of iron 75 inches wide and 1½ inches thick, making 20 cuts a minute. Auxiliary shears are attached for cutting the smaller scraps. One of the housings, a solid upright piece of iron made in one cast, weighs 17,000 pounds. Every particle of the machine was designed and made by the Linn Iron Company. It is the largest machine of the kind made in the South.

The Clymer Iron Company has been reorganized. Hon. Hiester Clymer is elected president, and Abraham Sweitzer treasurer. The board of directors is now composed of Hon. Hiester Clymer, George E. Clymer, William H. Clymer, George F. Baer, and Abraham Sweitzer.

The Thomas Iron Company has elected the following directors: Benjamin G. Clarke, Samuel Thomas, William W. Marsh, John T. Knight, Charles Stewart, Daniel Runkle, and Samuel Drake.

The Laclede rolling-mill, at St. Louis, which suspended operations several months ago, will be started up again during the present week.

In reply to a letter of inquiry, the *Bulletin* has obtained from Messrs. Anderson, Du Puy & Co. a complete description of their new crucible steel-works at Chartiers, a few miles from Pittsburg. The works are known as the Pittsburg Steel-Works. They were built in the winter of 1882–83, and the first steel was melted on April 11th, 1883. The works contain twelve heating-furnaces; ten trains of rolls (one 20-inch roughing, one 3-high 16-inch and one 3 high 20-inch bar, one 2-high 16-inch and one 3-high 16-inch sheet, and one 3-high 20-inch, two 10-inch, and two 12-inch plate); three hammers; and two 33-pot Siemens gas-furnaces and eight 16-pot steel-melting holes, allowing 194 pots to be used at each heat in the steel-works. The works have an actual capacity of 12,000 net tons of best tool, machinery, sheet, hammer, and agricultural steel, forgings, etc.

The Danville Nail and Manufacturing Company has completed and put in operation its new rolling-mill and nail-works at Danville, Pennsylvania. The building of the works was begun on February 1st, 1883, and on July 2d the puddle-mill started and on August 31st the first nails were made. The works consist of four double puddling-furnaces, one heating-furnace (capacity 300 tons), one 18-inch puddle and one 18-inch plate train of rolls, and 15 nail machines in place on August 31st. The nail-mill has an annual capacity of 60,000 kegs of cut nails and spikes.

The New Haven Rolling-Mill, at Fair Haven, Conn., was burned September 25th. Loss, $40,000.

The Cambria Iron-Works, at Johnstown, Pa., are engaged upon a contract for the United States government to manufacture steel bombshells of a tensile strength of 90,000 pounds.

The rod-mill of John A. Roebling's extensive wire-works, at Trenton, N. J., closed September 25th, and about ninety men are thrown out of work. The cause is the dullness of the wire trade. There is little doing in the wire department of the Trenton Iron-Works either, and many hands are idle.

The Norfolk & Western Railroad Company has had recorded contracts for building nine powerful engines, seven first-class passenger coaches, 100 box cars, and 700 coal cars, involving an outlay of several hundred thousand dollars. The Baldwin Works, at Philadelphia, are to build the engines, and W. C. Allison, of Hagerstown, and Bowers, Dure & Co., of Wilmington, the coaches and cars.

Reports from Conshohocken, Pa., state that the iron workers complain of receiving but few orders, and also the low price offered for iron. Still all the mills are running, making iron so as to be ready for any future demand.

Alan Wood & Co. are running all their mills on full-time, and employing 550 hands in the manufacture of plate, flue, and sheet-iron. About 300 tons per week of sheet and flue-iron are produced and 50 tons of muck bar.

J. Wood & Brother, manufacturers of sheet and plate-iron, also complain of a falling off in orders during the past three weeks, but still they have all their mills in operation and give employment to about 250 hands.

The establishment of John Wood, Jr., for the making of boilers, rolling-mill machinery is running with its full complement of men. The same may be said of Bates & Son, who manufacture patent boilers.

The Conshohocken Pipe-Works Company has nearly completed its new mill for gas and other pipes by a newly patented process. Experiments in the manu-

Digitized by Google

facture have been made here for some time. The pipes are made of uniform size, and then drawn out to the various sizes needed.

After an idleness for some time, owing to repairs, the Terre Haute Iron and Nail Company has signed the $6 scale for boiling (Fifth-District scale), and the mill has again resumed operations.

The Lake Superior Iron-Works being the lowest bidder, have received the contract for building 184 iron jiggers, which are to replace the wooden washers in the Calumet & Hecla stamp-mills. The Eureka Iron-Works being the lrwest bidder, has received the contract for furnishing a number of Evans's slime-tables, ten heads of small cam stamps to crush coarse sand, and some other iron work required in the contemplated enlargement and improvement of the company's dressing-works.

GENERAL MINING NEWS.

ARIZONA.

GRAHAM COUNTY.

In the Greenlee Gold Mountain District, about 150 claims have been taken up and the work of developing some of the richest claims has already begun. Several shafts are sinking.

PARKER GROUP.—The mines situated about three miles from the new silver strike, in Placer Gulch, between the San Francisco River and Chase Creek, one mile east of the Metcalf Mountain, comprising 37 claims, are very rich properties. These are principally copper prospects, carrying also a good per cent of gold and silver. The ledges are large and well-defined, and in width from 10 to 14 feet. About $1500 have been expended in developing these claims during the past two months.

SHOT.—On this copper claim, a tunnel has been driven 60 feet, having cut a good galena silver ledge. On the surface of this claim, there are six feet of loose dirt, carrying considerable shot copper, which can be panned out.

PIMA COUNTY.

GUNSIGHT.—A circular issued to the stockholders states that the mining properties sold at sheriff's sale recently at Tucson have been purchased by Hudson & Co., creditors of the company, and that the property may be redeemed on payment of Hudson & Co.'s debt. The result of the special meeting held at Camden, N. J., recently, for the purpose of considering the redemption of said property, has not yet been made known.

CALIFORNIA.

PLUMAS COUNTY—GREENVILLE DISTRICT.

EMERALD.—This mine improves steadily as it is opened up. The ledge is now developing from points distant from each other between six and seven hundred feet, and the ore prospects equally well at each point.

GREEN MOUNTAIN.—The old mill has been shut down. This change reduces the number of stamps in use to sixty, the entire capacity of the mill. This part of the milling capacity is fully supplied with ore. Work in the big tunnel goes on. The drift has now been run on the ledge a long distance, and though the rock shows gold, yet it is hardly rich enough to mill. The Blake chimney is yet about seven hundred feet distant, and the drift is progressing at the rate of eight and a half feet per day. The body of ore in the chimney is large, and there is some talk of adding forty stamps to the new mill when it shall be reached, and leave the old mill, with its thirty-two stamps, entirely unused. When the Blake chimney shall be opened, all of the ore from the upper levels can be sent down that way, and worked to better advantage in the new mill than in the old. The greatly increased fall would give a more economical use of the water, and there would also be a gain in labor from having all the work done in one building.

SIERRA COUNTY.

COLUMBO.—This ledge, located west of the old Independence claim, was recently purchased by an Eastern company for $27,500. Operations are pushed vigorously and various buildings are erecting. The twenty-stamp mill now building 800 feet below the tunnel will probably be in running order by November.

MARGUERITE.—Reference to our last issue will show that the Downieville *Times* had given very unfavorable statements regarding this property. In the latest number of this paper, it is stated that the property had a bright outlook, and that it was self-sustaining.

SIERRA BUTTES.—No. 9 tunnel, which was started last year, is on a level with Sierra City, and will eventually be run 9000 feet. At 6000 feet, it is expected the pay ledge will be struck, which is now worked 1000 feet below the upper tunnel. Three thousand feet of iron pipe are laying in tunnel No. 6, for the purpose of conveying water to furnish power for running hoisting-works between Nos. 7 and 8 tunnels. The ore will be hoisted from No. 8 to No. 7 tunnel, where the mill is located, until such time as connection is made with No. 9 tunnel and the mill is built at that point. The foundation for the sixty-stamp mill at this tunnel is already laid. The mill will not be completed before next season.

CANADA.

PROVINCE OF NEW BRUNSWICK.

BELLIVEAU.—Boring is progressing at these mines, with good prospects of success. At 266 feet depth, a deposit of a light colored shale was met. It burns as brightly as albertite and leaves a soft black residue, looking like black lead.

ONTARIO.

An unusually large amount of capital is investing in the development of minerals in the county of Ottawa. This season, the output of phosphate will exceed by a very large percentage last year's operations. Active preparations are making for the immediate working of extensive iron deposits.

EMERALD.—A half-interest in this phosphate mine, owned by the estate of the late E. W. Murray, has been sold for $40,000.

UNION.—This company, composed of American capitalists, intends to ship 4000 tons of phosphate from its mines in Ottawa County this season. The price of phosphate ranges from $15.60 to $16 per ton.

QUEBEC.

From Montreal, it is reported that a large amount of phosphate has been shipped from that port since the opening of navigation, probably larger than for any corresponding period of former years; and from present appearances, the export of phosphate this year will exceed any thing before experienced in the trade. Although the market can not be called active, a fair volume of business is reported on the basis of from $15.50 to $16.50 per ton, the sale of a lot of 200 tons being mentioned at $16.50 ex cars for about 75 per cent ore.

COLORADO.

CHAFFEE COUNTY.

An important gold strike made in the vicinity of Granite has created a good deal of local excitement, though the exact whereabouts of the find has not been divulged.

CLEAR CREEK COUNTY.

BONANZA.—The tunnel which is running to intersect the Fred Rogers mine has attained a length of 600 feet, and the work goes ahead uninteruptedly. It is 300 feet beyond the crossing with the Jordan lode. There yet remain over 300 feet to go before the Fred Rogers is reached. It is expected in that distance to open up two or three other lodes.

CHAMPION & DONALDSON.—For the month of August, the mines yielded $6000 from eighty-five tons of smelting ore. In addition to this, the bulk of the concentrating ore from both mines, pending the completion of the mill at Fall River, has been saved. At the Champion, 150 tons of concentrating ore are ready for shipment.

FREELAND.—In the west lower level, three feet of solid mineral were struck. Assays were 21½ of gold and silver 22 ounces. Colonel Osbiston states that this is the largest body of ore ever found in the mine and the highest grade mineral.

NEW YORK MINING AND MILLING COMPANY.—The 150-ton stamp and concentrating mill is inclosed. Half the machinery has arrived, including a 120 horse-power Corliss engine, two seventy-five horse-power boilers, ten batteries, etc.; the remainder is hauling from Lawson as fast as possible. The ore is dumped into the top of the mill from a 500-foot tramway leading to the Big Chief tunnel, now 120 feet in and gaining depth foot by foot. Ore carrying $5 per ton will pay, the company asserts. All tests so far show the ore to carry $40. It is crushed, carried by gravity to the ten batteries, each of which has five stamps, and thence to the plates. The tailings are to be concentrated by twenty Frue vanners.

SEVEN-THIRTY.—During the month of August, the shipments, largely from development-work, aggregated 53½ tons of smelting ore, netting $126 to the ton, or about $6700. At present, the main shaft is 390 feet deep from the surface, with four levels below and three above the cross-cut tunnel. These levels are driven at intervals of from sixty to eighty feet, and together measure over 6000 feet. Just below the tunnel, a rich body of ore was stoped for fifty feet, returning $50,000. Adjoining this, is a reserve of equal length and apparently the same value. In driving this level 900 feet, mineral in paying quantities was encountered the whole length. Work is progressing in three of these levels day and night, in two by day only. In the second level below the tunnel, the most recent mill-runs have made returns of over $700 per ton. On the east, in the third level, there is a reserve of 175 feet, the ore-body being continuous the whole length of the drift, varying in width from six inches to two feet. No stoping has been done on this ore-body, which, although at first of low grade, has now improved, showing increased value in the breast. The last extracted gives 61 per cent in lead and 61 ounces in silver. The machinery is all on the ground and is in running order.

SILVER GLANCE.—The hoisting machinery has arrived, and will be in operation in a short time. This property is producing large quantities of ore at present, and, with the aid of machinery, will able to ship much more.

SILVER PLUME.—The mill runs steadily, treating from 12 to 18 tons per day.

SNOW-DRIFT.—This mine is said to be paying handsomely. The property is worked under a lease. On the level east of the Snow Drift tunnel, drifting and stoping are prosecuted with flattering results. This level is 550 feet in length, and shows up a six-foot crevice with a pay-streak averaging all the way from one and a half to fourteen inches of solid mineral, carrying sulphurets, galena, and gray copper, which averages over 200 ounces silver per ton to each mill-run. A distance of 70 feet below the tunnel level, another party of lessees have started a drift east. They have a continuous body of mineral of the same character as that above named. At a point fifty feet above the tuunel level, there are four parties of lessees at work drifting and stoping on a superior quality of ore, and taking out splendid pay. In the Good Hope level, sixty feet above, a lease has been let to drift east.

GILPIN COUNTY.

CALIFORNIA.—In the 1400-foot level, the pay-streak has widened out from two to six feet. The grade of this new body of ore is higher than any heretofore obtained. The smelting ore in the new streak is two feet in width. Tests of the ore just struck give returns of two ounces of gold to the ton. Thus, the present output of $5000 a week will be still further increased. The California is the deepest mine in Colorado.

GREGORY.—This stamp-mill, in Black Hawk, has been closed down by the California Mining Company, whose mill-dirt from the California mine will hereafter be crushed at the Hidden Treasure mill. It is understood that Central parties are negotiating for a lease of the Gregory mill, which will resume work immediately.

LAKE COUNTY.

ANTIOCH.—The gold mill is to start up shortly on ore from the Mosquito range.

AZTEC.—Shipments from the ore accumulated have been received. The property is worked through the old Kennebec shaft, and the mineral is found at a depth of about 180 feet from the surface.

CHRYSOLITE.—The Muldoon shaft has been re-leased. The parties holding the new lease have put up a Joplin whim, and are working vigorously.

CROWN POINT & PINNACLE.—These mines, situated at Rock Hill, have been sold for $40,000.

ELGIN SMELTING-WORKS.—The two furnaces in Big Evans Gulch are working very successfully. The establishment reduces from fifty-five to sixty tons of ore daily. Charges are run on twelve to fifteen per cent of lead, and eight to ten tons of bullion of very fair grade in silver are turned out daily. The ore-bins at the mine are all filled with ore, and the receipts at present are much larger than the regular consumption. In order to meet the increasing business of the establishment, the Manville Smelting Company, operating the works, has decided to erect another furnace immediately, and preparatory grading has been commenced with this object in view.

LITTLE CHIEF.—The company has received $22,500 from its mine since September 6th. The present output is about fifteen tons a day, running quite well in silver and gold, and averaging from fifty to one hundred dollars a ton. The mine, it is stated, shows no material change, but is thought to be rather improving in character. It is still an open question whether the ore mass is a reliable, permanent chute or body of mineral, on which some dependence can be placed, or only an aggregation of pockets and seams which may play out at any time. The development of that portion of the mine likely to show a continuation of the pay mineral is advancing rapidly, and the probable future value of the new strike can soon be more definitely determined. A new shaft, designated as No. 6, was started some days ago, and is down about ninety feet. The No. 6 shaft is situated about forty-five feet from the north end line of the claim. A drift is also driving from the old north workings of the mine, to connect with this shaft.

MAID OF ERIN.—The lessees who have a lease on portions of the Maid of Erin not in conflict with the Vanderbilt lode have begun taking out considerable rich ore. The property is worked through the Big Chief shaft. From all that can be learned, the Maid of Erin shows a very large and solid body of sand carbonates, from which twenty to fifty tons of ore can be extracted daily without any effort. The mineral ranges from forty-five to sixty per cent lead, and much of it is literally covered with chloride of silver.

NEW PITTSBURG.—All the company's shafts, except the Keene, Bates, and Loomis, have recently been leased.

STONEWALL JACKSON.—This mine is worked ou a lease. The mineral produced is a carbonate of lead, with some iron, and shows chloride of silver. No shipments have yet been made, but assays show the ore to run from 20 to 300 ounces in silver to the ton, and to carry as high as sixty per cent in lead. The ore-streak as yet is small, but it has at times opened out to a hight of six feet, with a width of from six to ten inches.

LA PLATA COUNTY.

SOUTH PARK.—Of two shipments of ore to the Grand View smelter, one lot was paid for at the rate of 410 ounces of silver to the ton and 80 per cent lead;

Digitized by Google

the other lot at 990 ounces of silver and 14 per cent lead. The ore is sulphuret, wire silver, and galena.

OURAY COUNTY.

Ground has been broken for a thirty-ton concentrator on the San Miguel River, opposite Telluride. Most of the machinery is on hand, and with no serious delay the mill will be in operation on November 15th.

CROOKE MINING AND SMELTING COMPANY.—The output of the Ute and Ulé for August was 600 tons. Both mines promise well for the future. The new shaft from 3d level of Ute is 60 feet deep. Vein, four feet. The quartz is stratified with 10-inch streaks of mineral. The prospects for the opening out of the level below are good, and should the width of the vein continue in the level below as above, it will open stoping ground for two years at an output of 300 tons a month. The stopes in the mine are producing the usual quantity of ore. The Ulé drift west in 7th level continues its usual production of ore. This level has been drifted 250 feet over a fine body of ore. The stopes above are producing largely and give great encouragement for the future of the mine below. Up to September 1st, there were 2400 tons of concentrates stored in Lake City by this company.

PARK COUNTY.

NESTOR.—This company has made arrangements to build immediately a stamp-mill and concentrator at its mines, near the old town of Mosquito, and thus treat its own ores at a nominal expense. This will make the fifth mill and concentrator built in Mosquito Gulch in the past year.

PUEBLO COUNTY.

The oil excitement has reached Pueblo. A meeting was held there recently for the purpose of considering the subject of forming a company to put down a well in or near Pueblo. The greatest unanimity and enthusiasm prevailed. A committee was appointed to receive subscriptions, and another to secure leases. Ten thousand dollars will be raised to work a well 3000 feet if necessary.

SUMMIT COUNTY.

CABLE.—A streak of ruby silver ore has been struck in this lode. The streak appears from top to bottom of the tunnel. Further developments will be vigorously pushed to open up this extremely valuable streak of mineral. This ore has been struck after a "pinch" of 250 feet, with nothing but the walls to guide, through the hardest kind of gangue matter. The breast of the tunnel is now softening and a soft gangue streak coming in. The Cable was last year shipping ore, but has not shipped for six months.

MARK TWAIN.—The mine is shipping ten tons per day, but the superintendent reports that he has had to reduce this force this month one third, on account of a lack of shipping facilities by rail. If the facilities are furnished, or a track continued to Montezuma, the output could be made twenty-five tons per day.

IDAHO.

MORTON.—This mine, situated about five miles from Hailey, has been sold for $20,000.

MEXICO.

GUANACEVI MINING COMPANY—Mr. J. J. Downing writes us the following from Denver, Colo.: Guanacevi, a little mining town of a thousand souls, lies isolated from the world at an elevation of 8000 feet above sea-level, among the foot-hills of the Sierra Madre range, some 200 miles north of Durango City, and 75 miles south and east of the famous Batopilas mines. It is accessible only by bridle-paths over a low mountain pass. No wheeled vehicle was ever seen in its streets, nor, so far as known, an American before last summer. In the month of July, 1882, Messrs. I. W. Gift and B. N. Curtis, accompanied by Mr. Alfred R. West, a well-known mining expert and metallurgist, visited Guanacevi, and made a thorough examination of its silver mines. They discovered there an astonishingly rich mining district, which had been worked in the rude and indifferent manner peculiar to that country for two hundred years or more. It was not a region of prospects, but of actual mines, well developed after the Mexican system, with considerable working, large quantities of rejected low-grade ores on the dumps, and a number of native reduction-works of the arrastra and patio style. The inhabitants are a mining community, and have lived off the mines for generations back. Their large cathedral, built years ago from tithes on the product of the mines, and the thousands of tons of ore lying in sight, rejected by the arrastra process, which can not profitably work ore of less value than 40 ounces to the ton, are visible evidences of the richness and permanence of the ore-bodies; and yet to an American miner, the development of the mines seems only to have fairly begun. The Mexican workings are hardly more than shafts sunk vertically into the veins not to exceed generally from 150 to 200 feet. Hoisting-works are seldom used, and pumping machinery is unknown. They are dry mines; but if the water runs in during the rainy season, it has to be taken out by hand in buckets, or left to dry out, or the shaft is abandoned for a new one. The natives lack enterprise and resources. They think God is unjust to them because he does not make the water run out as well as run in. The assays herewith given were carefully made in duplicate by Messrs. West and Gift from a very large number of samples of ore selected by themselves from all parts of the old workings of the several mines. They are believed to be below a fair average. Messrs. Gift, Curtiss, and West descended into and examined all the mines except two, and those two, according to local reports, are the most valuable in the group. Want of ropes and ladders prevented access to them. But from old miners who had worked in the mines, they learned that at the death of the former owner they were taking ore from a chimney averaging 100 marks to the carga, equal to $800 for each 300 pounds of ore. The other had been abandoned since the death of its former owner, and had gradually filled with surface water. But the assay of ores from the adjoining extensions of the mine, north and south, show 340 ounces to the ton. These facts are a meager summary from the report made by Messrs. Gift and Curtiss on their return, upon which was based the purchase of the entire group of seven mines and the organization of the Guanacevi Mining Company. The veins are well-defined, from ten to thirty feet between walls, and are capable of producing large quantities of rich ore. One of them, the Santa Cruz, has an ore-body sixty feet wide. The mines have all been worked more or less by the former Mexican owners, in their rude way, and have produced large amounts of bullion. I think there is sufficient ore in sight in these old workings, and in the pillars left standing, to more than pay for the entire property. The Mexican manner of working takes from fifteen to seventeen days, and costs from $27.50 to $28 per ton. But I think that any good metallurgist will bear me out in saying that a good American mill would extract the silver from a vastly greater quantity of ore in twenty-four hours, at a cost not exceeding ten dollars per ton. Miners' wages are from seventy-five cents to one dollar a day, and wood and water are plentiful on the mountains.

MICHIGAN.

AGOGEBIC.—The shaft is down fifty feet, it having gone through the slate into good clean ore, samples of which are said to be very pure. A drift has been started north from the bottom of the shaft.

AHMEEK.—An examination of a fissure-vein on this mine is going on, and the developments so far are satisfactory to a degree. At the point attacked, the deposit is not very wide, but is exceedingly rich in copper, some two tons of barrel work having already been taken from a limited space.

ROPES GOLD AND SILVER MINING COMPANY.—The production of a brick of bullion, the result of the first hundred tons run at this company's stamp-mill, has created great excitement at Ishpeming. The official report made by the stockholders regarding their first run shows: Products from amalgam: Gold, weight, 34·073 ounces troy; value, $704.62. Silver, weight, 89·83 ounces troy, value, $98.81. Concentrates: Gold, weight, 6 ounces; value, $126.14. Silver, weight, 68 ounces, value $74.80. Total product, $1004.37. Value of tailings: In first part of run—gold, $9 per ton; silver, $2.72 per ton; total, $11.72 per ton. In last part of run—gold, $6 per ton; silver $1.92 per ton; total, $7.92 per ton. The value of the product of the first 60 tons, as shown by assays of both amalgam and concentrates, gave an average of only about $6.50 per ton, and the last 40 tons about $14.85 per ton. This was caused partly by working rock rather below the average on the start, partly by the absorption of the amalgam by the plates and battery, and also largely by the too limited use of mercury. This is shown conclusively by the increase of the product of the last 40 tons, which was almost entirely from the free-milling product.

MISSOURI.

At a depth of about sixteen feet, a body of mineral was struck in a prospect-shaft recently sunk near Jericho. The parties interested in the mining operations selected about five or six hundred pounds of the ore containing the sulphurets, and sent it to Kansas City for treatment. The returns were so favorable that they immediately proceeded with work, and it is said have sent for a crusher to reduce the ore, and are making active preparations for work on a large scale. The men engaged in the mining operations claim to have struck the right ore in five or six different places in the vicinity.

MONTANA.

BEAVERHEAD COUNTY.

VIRGINIA CITY.—The object of the company is to open up and operate, by bed-rock flume, an extensive claim in Grasshopper Creek, below Bannack. Representatives of the company who have prospected the ground say that good pan prospects were obtained, and that there is no doubt but the enterprise can be made to pay. Nothing more than preliminary work will probably be undertaken this fall, as the season is now so far advanced that but little could be accomplished before the setting in of winter.

DEER LODGE COUNTY—FLINT CREEK MINING DISTRICT.

GRANITE MOUNTAIN.—Work will be commenced on the lower tunnel as soon as the air-compressor can be got to work. The buildings are near the mouth of the lowest working tunnel. This adit, when completed, will tap the mine at a vertical depth of 800 feet. Burleigh drills will be used to drive the heading. The company has made no arrangements to build a mill yet, deeming it safe and proper to thoroughly and systematically explore the mine first. The Algonquin mill, at Hasmark, is running steadily on Granite ore.

HOPE.—The diamond drill has struck a fine body of high-grade ore. A two-compartment shaft is to be sunk to explore the new prospect.

JAMES G. BLAINE.—Clark, Merrill & Co. are sinking on this lode, west of the Granite Mountain. Some very high-grade ore has been taken out of the vein. The shaft is down 80 feet, with plenty of water in the bottom.

SILVER BOW COUNTY.

ANACONDA.—It is reported that this mine is opened up for a length of 1400 feet. On the 400 level, it is 45 feet wide at one point. It has 60,000 tons of ore on the dump. It has just contracted for the sale of 5000 tons of 50 per cent copper ore in the old country, where it is to be shipped. The rich copper ore occurs in bunches and chutes, and carries but little silver.

NEVADA.

EUREKA COUNTY.

LIMESTONE No. 1.—A Philadelphia company, which recently acquired interests in the Limestone district, has let a contract to sink a shaft 100 feet deep on an extension of the Limestone No. 1, which is owned principally by railroad men. The original location on the Limestone lead has been prospected to a depth of 100 feet by a shaft. The lead shows 10 inches of galena ore that assays over $100 to the ton in silver and carries 60 per cent of lead from the sagebrush roots down. In sinking the shaft, some 25 tons of ore were extracted that will pay the expenses incurred in prospecting the mine. The company continues to work steadily, and the trustees have ordered the shaft sunk another hundred feet.

ONONDAGA.—The company has decided to put up reduction-works on the Humboldt. The nature of the works will be determined by the nature of the ore as found in further explorations. The prospect-shaft, sunk on an incline of about 30 degrees from the perpendicular, is now down 135 feet in ore. Iron continues to be the gangue, but in this formation occur yellow carbonates, also native silver, which was not to be seen near the surface. The proposition is, to sink about 100 feet farther, and then complete the tunnel which was started to strike the shaft at the proposed depth. This tunnel is now in 200 feet, and will have to be run in 300 feet farther. It is calculated that it will cost 25 cents per ton to dump the ore through this tunnel into the cañon. About five feet are made per day, and it is expected that in about twenty days the shaft will be sunk to the proposed depth.

ZANOLI.—On the 50-foot level, the ledge has been stripped 45 feet northwest and 45 feet southeast on a body of high-grade yellow carbonate ore. The same work has been done also on the 80-foot level, on which the ledge, perfectly defined and with smooth walls, varies in width from one to seven feet. The mine has been prospected to the depth of 112 feet, the ore going all the way to the bottom in quantity and quality as above; but water has come in and stands 50 feet deep in the incline. The ore is piled on the dump without making any shipments. It is proposed to run a tunnel in to strike below the incline at a depth of 300 feet from the surface to drain the mine. It is expected, if the mine holds out, to erect works.

STOREY COUNTY.

ALTA.—Very rapid progress in the work of draining the mine is made. They will now soon have won their way to a foothold on the 1450 level, when there will remain but 700 feet to be freed of water.

BRUNSWICK.—The expensive improvements making to this mill, on the Carson River, says the Eureka *Sentinel*, would indicate that some one still has faith in the Comstock. The mill has received a thorough overhauling, and many thousands of dollars have been spent in the way of new machinery and repairs. Steam power is being placed in the mill: therefore, in the future, there will not be a total cessation of ore extraction upon the failure of the water in the river.

NEW MEXICO.

A recent dispatch from Las Vegas says that the placer mines, discovered near Silver City years ago by a man named Adams, whose party were massacred by Indians with but one man escaping, have again been found and are creating considerable excitement. The placers are noted for their large and plentiful nuggets of gold, and years have been spent by prospectors in searching for the lost fields whose history has become an almost everyday story, and but little confidence has been placed in the truth of the statements of the surviving party who has devoted all this time to scouring the mountains in his unrelenting energy to discover the diggings once so well known to him. At last, the lost fields are reported found, and parties started on horseback heading for the White Mountains, where the placers are supposed to be. Word has come in from Camp

Digitized by Google

Fleming that one of the lucky finders arrived in camp with a half-pound of gold nuggets. The excitement spread with the report, and the town is nearly depopulated.

CARLTON.—The stamp-mill at Silver City has been purchased by J. Fleming, who will start up the works after a long idleness.

CINCINNATI.—This mine is making a good showing, and 100 tons of ore have been shipped which ran 120 ounces in silver and over 30 per cent lead per ton, and there is still on the dump as much more ore of lower grade, waiting for the completion of the new smelter at Deming.

SANTA RITA.—The copper-works have been shut down since last April. It is understood that there are to be some important changes in the machinery which have been found necessary. Cornish rolls will probably take the place of the stamps now in use, and every thing will be overhauled generally and put in complete order for a permanent business. Tons of leaf and kidney copper and concentrates may be seen in different parts of the mill, which will be utilized as soon as things are in thorough condition for steady working. The company owns 56 patented claims, and now has apparently a large body of ore in the immediate vicinity of the mill at the depth of 300 feet from the surface. In many of the properties, considerable prospecting has been done with a diamond drill, and in one instance, at 800 feet, a body of water was reached which will rise 100 feet above the surface. The company has an abundant supply of mineral and water within easy reach upon which it may begin operations as soon as its arrangements are completed.

PENNSYLVANIA.

The people of Canaan Township, Wayne County, are considerably worked up over the alleged discovery by a Colorado miner of a vein of silver ore on the farm of Stevens Delaney. The man who discovered the ore is an experienced prospector, having worked a long time in Leadville and Denver, and he says the ore is rich enough to pay a large interest on the money that must necessarily be invested in order to properly mine the ore. A stock company and a stamp-mill are in contemplation.

AMERICAN IRON MINING AND GAS COMPANY.—This newly organized company, with a capital stock of $1,000,000, intends to work the iron ore veins of Plum Creek District, and bore for gas. If there is sufficient inducement, the Alleghany Valley Railroad Company will build a branch road through the district. Mr. John Kaiser, of Pittsburg, is president, and Mr. R. H. Harris, of Philadelphia, secretary and treasurer.

SOUTH CAROLINA.

A report states that Mr. J. W. Seacrest, who has had considerable experience in developing gold mines, has taken a new departure in gold mining, and will shortly begin tapping the rock bottom of the Broad River, at Smith's Ford, in York County, for the precious metal. There is an old river-bed at that point which has been dry ever since the war, and Mr. Seacrest proposes sinking shafts through the soil to the rock bed, where he will find the gold. This is called the river washing. The gold is found under the sand, on the rock, where it settles by gravitation.

UTAH.

CACTUS.—An important strike has been made. The body of ore tapped is said to be large and much richer than any thing heretofore found in the mine. The concentrating-works at the Cactus have been lately improved and are doing excellent work. Shipments of ore are made, the ore going to Colorado for reduction.

SALT LAKE COUNTY.

EMMA.—Work progresses satisfactorily. The shaft sunk 1700 feet from the mouth of the Bay City tunnel has attained a depth of 200 feet. From this shaft a cross-cut was run at the 135-foot level, a distance of 200 feet, cutting the vein. On the vein, drifting has been done both east and west, each drift at present having gone 100 feet on the vein. These drifts are 200 feet vertically below the old workings of the mine, from which so much wealth was taken a few years ago. Ore is taken out and sent to the smelters, but the most of the work is done for the purpose of developing and getting the property in condition for extracting the ore easily. The east drift is in very interesting ground, which is looking better and better as progress is made. The shaft is to be sunk 200 feet deeper, where it is expected to cut the vein at a point 550 feet vertically below the old workings and 800 feet on the dip of the vein. Twenty-eight men are employed on the property, and as large a force will be worked all winter. The Denver & Rio Grande is taking up to Alta enough coal to operate the machinery and for other purposes till next June, so that work will not have to be suspended should the tramway become blocked, as is usual in the winter. The pumps keep the mine free from water, the discharge being from 15,000 to 18,000 gallons per hour.

SILVER MOUNTAIN.—The appearance of the mine has shown a decided improvement recently. The shipments of ore have begun. The ore is hauled to Sandy, a distance of twenty miles, at a contract price of $20 per ton. As it is worth $100 per ton, there is a large margin left for the company. The ore assays seventy-five ounces silver, $15 in gold and 45 per cent lead. Work will be done during the winter running drifts and opening up the ore-bodies, so that the extraction of ore next season can be rapid.

WAHSATCH COUNTY.

SOUTHERN TIER.—This company has been formed by Eastern capitalists with a capital of $2,000,000. The mines are in Snake Creek District. Work will soon begin on a new tunnel designed to tap the vein at a depth of between four and five hundred feet, which will take several months for completion.

WASHINGTON COUNTY—TUTSAGUBIT DISTRICT.

This new mining district has been located midway between the Santa Clara River and Beaver Dam Wash and on both sides of the old California road. Fifteen claims have since been located. These claims are situated, some on the side and some on the crest of one of the Santa Clara Mountains. A vein of carbonite ore, bearing lead, silver, and gold, crops out in all these locations, which extend along the mountain two miles or more.

MOUNTAIN CHIEF.—This company owns the following claims: Mountain Chief, Black Warrior, Whip-poor-will, Black Hawk, Red Warrior, Mammoth, Cherokee, and Gray Eagle. The first-named claim has been worked since May. A tunnel 38 feet long has been run in the side of the mountain to tap the vein, which dips at an angle of 90 degrees. At the Black Warrior, a vein of carbonate ore crops out. The ore among the grass-roots assays from 72 to 80 per cent lead, from 12 to 38 ounces silver, and some gold. Two or three hundred feet are cleared off and exposed to sight, and a 40-foot tunnel run into the mountain. Since the formation of the company, all work has been transferred to this claim, it being the most accessible. A road to within half a mile was easily made; the remaining portion, though difficult and expensive, will soon be completed. A tramway, 200 feet long, will deliver ore on this road. At the Santa Clara River, twelve miles distant, ground and water have been purchased, and a smelter will be soon put up.

WYOMING.

BOSS.—This mine at Cummins is worked night and day. It has been developed by a shaft some fifty-seven feet. The general trend of the lead is north and south, shows a well-defined foot-wall, and vein-matter of the width of fifteen feet, no hanging-wall as yet having been reached.

PATENTS GRANTED BY THE UNITED STATES PATENT-OFFICE.

GRANTED AUGUST 7TH, 1883.

282,480. Speed-Governor for Steam-Engines. David E. Adams, Pittsburg, Pa., Administrator of James D. Willoughby, deceased.
282,487. Speed-Indicator. Thomas Blanchard, Stoughton, Mass.
282,512. Blast-Furnace. James J. Fronheiser, Johnstown, Pa.
282,518. Core for Casting Steel. James A. Herrick, Cleveland, O.
282,531. Apparatus for Cleaning Oil-Wells. William E. Karns, Parker's Landing, Pa.
282,543. Coal, Iron Ore, and Merchandise Derrick. William E. Ludlow, Sandusky, O.
282,555. Unloading and Handling Coal. John R. McPherson, Seabright, N. J.
282,556. Hoisting Apparatus. George E. Newell and Loren G. Ladd, Pawtucket, R. I., Assignors to Smith Grant & Co., same place.
282,565. Furnace-Grate. John A. Price, Scranton, Pa.
282,575. Draught-Equalizer. Benjamin C. Shaw, Toledo, O.
282,586. Regenerator-Furnace. William Swindell, Alleghany City, Pa.
282,604. Apparatus for the Manufacture of Bituminous Coal Coke. John F. Bennett, Pittsburg, Pa.
282,632. Mining-Machine. Martin Hardsocg, Avery, Iowa.
282,686. Rock-Drilling Machine. Thomas Threlfall, San Francisco, Cal., Assignor to James Watson, same place.
282,687. Rock-Drilling Machine. Thomas Threlfall, San Francisco, Cal., Assignor to James Watson, same place.
282,728. Process of Annealing Chilled and other Iron Castings. Edwin Jenkins and Alexander Law, Melbourne, and William Price, Carlton, Victoria.
282,750. Drilling-Machine. James Miller, New York City, Assignor of one half to Cornelius H. Delamater and George H. Robinson, same place.
282,751. Coal-Car. James A. Millholland, Cumberland, Md.
282,803. Ore-Roasting Furnace. Robert L. Thompson, Boulder, Colo.
282,845. Steam-Boiler Furnace. Edward Clark, New York City.
282,863. Process of Grinding and Apparatus for Amalgamating Ores. Charles H. Dow and William H. Chandler, Virginia City, Nev., Assignors of one half to William A. Shreves, Bordentown, and Myron L. Justin, Jersey City, N. J.

GRANTED AUGUST 14TH.

282,982. Machine for Amalgamating the Gold and Silver in Pulverized Ores. William E. Harris, New York City.
283,064. Steam-Pump. James H. Blessing, Albany, N. Y.
283,074. Manufacture of Wrought-Iron. Lucius D. Chapin, Chicago, Ill.
283,075. Metallurgic Furnace. Lucius D. Chapin, Chicago, Ill., and Lebeus C. Chapin, Kalamazoo, Mich.
283,077. Process of Treating Lead to Impart to it the Property of Adhering to other Metals. Francis J. Clamer, Philadelphia, Pa., Assignor of one half to Joseph G. Hendrickson, same place.
283,098. Water-Jacket for Metallurgic Furnaces. Charles E. Gore, Lafayette, Ind., Assignor of one half to Samuel E. Ogden, Columbus, O.
283,101. Steam Vacuum-Pump. Georg A. Greeven, Bruehl, Prussia, Germany.
283,107. Tuyere for Blast-Furnaces. Gustav Hilgenstock, Hoerde, Germany.
283,136. Method of Bending Angle-Iron. Moses Mosler, Cincinnati, O.
283,141. Process of Manufacturing Crucible Cast-Steel. Jacob Reese, Pittsburg, Pa.
283,153. Rotary Pump. George W. Sharp, Buffalo, N. Y., Assignor to Augustus M. Westfall and Edgar A. Gay, same place.
283,156. Apparatus for Washing and Delivering Coal, etc. Charles Sheppard, Bridgend, County of Glamorgan, England.
283,180. Ore-Feeder. William E. Wild, San Francisco, Cal.
283,184. Brick-Machine. William Woodward and Abel B. Woodward, Nashville, Tenn.
283,198. Machine for Cutting and Punching Metal. Joshua Edwin Lane Bradeen, South Berwick, Me.
283,234. Process of and Apparatus for Manufacturing Water-Gas. William W. Gibbs, New York City, and J. Y. McClintock, Malden, Mass., Assignors, by Direct and Mesne Assignments, to the United States Gas Improvement Company, of Pennsylvania.
283,241. Process of Purifying Iron and Condensing the Products. James Henderson, Bellefonte, Pa.
283,262. Dumping-Wagon. William Leonhardt and John H. Leonhardt, Baltimore County, Md.
283,286. Mine Air-Regulator. James Sawyer, Freeburg, Ill., Assignor of one half to Washington de Bolt, St. Louis, Mo.
283,296. Ore-Separator. Charles St. Charles, New York City.
283,336. Attachment for Boiler Furnaces. George S. Gilbert, Baltimore, Md., Assignor of one third to Thomas M. Broderick, same place.

REISSUE.

10,367. Mode of Plating Iron and Steel. Hermann Reusch, Dillingen-on-the-Saar, Prussia, Germany, Assignor to Carl Reusch, New York City.

GRANTED AUGUST 21ST.

283,366. Brick-Machine. James C. Anderson, Highland Park, Ill.
283,419. Furnace-Grate. Harry Rogers, New York City.
283,435. Tuyere for Forges. Nils O. Swenson, Lead City, Dak.
283,461. Process of Roasting and Disintegrating Gold and Silver Ores. David W. Birmingham, Clifton, N. Y.
283,483. Process of Manufacturing Iron and Steel. James Henderson, Bellefonte, Pa.
283,484. Art of Manufacturing Iron and Steel. James Henderson, Bellefonte, Pa.
283,488. Machine for Perforating Sheet-Metal. John W. Hyatt, Newark, N. J.
283,509. Drill. John H. Pendleton, Brooklyn, Assignor to himself and Nelvil W. H. Hix, New York City, and Alexander H. Tiers and Cornelius Tiers, Madison, N. J.
283,540. Amalgamator. Henry T. Vanderhoof, New York City, Assignor, by Mesne Assignments, to the Hamilton Lead Bath Company, same place.
283,577. Bessemer Converter. Thomas Crowe, South Chicago, Ill.
283,600. Smoke-Consuming Device. William Perry Hall, Piqua, O.
283,604. Dumping-Cart. Thomas Hill, Jersey City, N. J.
283,643. Charcoal-Kiln. Charles S. Nellis, Chittenango, N. Y., Assignor of one fourth to Thomas P. Hull, same place.
283,708. Boiler-Furnace. William P. Hall, Piqua, O.
283,735. Manufacture of Steel. John Gjers, Middlesborough-on-Tees, County of York, England.

GRANTED AUGUST 28TH.

283,783. Basic Process of Manufacturing Iron and Steel. James Henderson, Bellefonte, Pa.
283,809. Steam-Jet for Smoke-Consuming Furnaces. Sidney Parker, Chicago, Ill.
283,830. Apparatus for Pulverizing Grain, Ores, etc. Francis Taggart, Brooklyn, N. Y.
283,857. Radial Drilling-Machine. Alfred Box, Philadelphia, Pa.
283,858. Mining-Machine. Andrew Brandenburger, William Tirre, and Hermann Barditzky, St. Louis, Mo.
283,901. Apparatus for the Manufacture of Oxide of Zinc. Mark Lambert, Newark, N. J.
283,937. Dump-Wagon. George M. Wallace, Yuba City, Cal.
283,943. Brake and Truck for Mining-Machines. Benhard Yoch, St. Louis, Mo.
283,955. Device for Operating Air-Compressor Valves. Charles A. Bennett, Dover, N. J., Assignor of one half to the Morris County Machine and Iron Company, same place.
283,999. Process of and Apparatus for the Treatment of Iron and Steel. Joseph Pearson Gill, New York City.
284,000. Process of and Apparatus for Producing Non-Corrodible Surfaces on Iron and Steel. Joseph Pearson Gill, New York City.
284,001. Surface of Iron and Steel. Joseph Pearson Gill, New York City.
284,004. Making Steel Castings. William Hainsworth, Pittsburg, Pa.
284,005. Bessemer Plant. William Hainsworth, Pittsburg, Pa.
284,006. Process of Manufacturing Steel. William Hainsworth, Pittsburg, Pa.
284,059. Process of Manufacturing Charcoal and Kiln therefor. Henry M. Pierce, Chicago, Ill.
284,063. Process of Extracting Metals. Isaiah L. Roberts, Jacksonville, Fla.
284,067. Diamond Drill and Well-Sinking or Boring Safety-Machine. Gilbert McM. Ross and Daniel Grant, Virginia City, Nev.
284,074. Iron Wheel. James L. Schruben and William F. Leonard, Lafayette, Ind.
284,101. Bacasse-Furnace. Daniel Wilde, Washington, Iowa.
284,123. Process of Reducing Ores. Joseph Pearson Gill, New York City.
284,135. Roller-Mill. John Livingston, Dayton, O., assignor to Stout, Mills & Temple, same place.

REISSUE.

10,374. Air-Pump. Charles Moore, Philadelphia, Pa., Assignor, by Mesne Assignments, to Hydro-Pneumatic Pump Company, New York City.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Sept. 28.

The mining market this week has been very dull and almost featureless. The Leadville stocks, which attracted so much attention last week, were very quiet and showed signs of weakness, owing to most of them selling ex dividend. The fancy stocks were also neglected very much this week, although prices suffered no material change. Below will be found a full summary of the market. The total number of shares sold aggregates 107,890 shares, as against 236,335 last week.

The Comstock shares were very quiet at steady prices. California was quiet and steady at 18@20c. Sierra Nevada was irregular, with a small business, selling from $3.85@$4.10@$3.90. Union Consolidated was quiet and steady, selling from $4.75@$4.90. Consolidated Imperial was irregular, selling from 6@4@5c. Sutro Tunnel was very quiet at very irregular prices ; it sold from 20@18@25@20c.

The Leadville stocks were moderately dealt in and were steady. Amie was very active at steady prices, selling from 21@20c., dividend unpaid, and from 13@17@15c. dividend paid. Chrysolite was quiet and steady, selling from $1.30@$1.25. Dunkin sold from 27@25c., with a small business. Breece sold at 18c. Iron Silver was moderately dealt in at strong prices ; it sold from $3@$3.20. Leadville was weak, under a small business, selling from 50@42c. Little Chief was moderately dealt in at irregular prices ; it sold at 75c. dividend unpaid, and from 66@55@60c. dividend paid. Little Pittsburg was weak, under a small business, selling from 70@60c. Climax sold from 12@11c., with moderate transactions.

The Bodie stocks were very quiet at steady prices. Bodie Consolidated sold at 60c. Standard was quiet and strong, selling from $5.63@$6. Bechtel sold at 7c.

The Tuscarora stocks were also quiet and steady. Belle Isle sold at 30c. Navajo records but one small transaction at $3. North Belle Isle was quiet and steady, selling from 40@45c. Elko Consolidated was moderately dealt in at steady prices, selling from 10@9c.

In the miscellaneous list, Alice was stronger, with a small business, selling from $2.40@$2.70. Eureka Consolidated was quiet and steady, selling from $5.25 @$5.63. Hall-Anderson was moderately dealt in and was a little weak ; it sold from $1.20@$1.10. Horn-Silver was quiet and steady, selling from $6.88 @$7. Hukill was irregular, selling from 5@7@6c., under a small business. Northern Belle was quiet and steady at $5.63. Robinson Consolidated was but moderately dealt in and was steady ; it sold from 43@40c. Sierra Grande was quiet and steady, selling from $1.15@$1.20.

Barcelona was moderately dealt in and was weak ; it sold from 39@32@33c. Bradshaw was irregular, with a small business, selling from 25@20@23c. Central Arizona was quiet and steady, selling from 30@ 39@35c. Decatur was quite active at steady prices, selling from 2@4@3c. Eastern Oregon was actively dealt in at steady prices ; it sold from 46@48c. Harlem was weak, under a small business, selling from $1.25@99c. Hortense sold from 9@10c., with small transactions. Oriental & Miller was quiet and irregular, selling from 11@ 9@10c. Rappahannock sold at 6c. Sonora Consolidated was but moderately dealt in, at steady prices ; it sold from 26@28c.

MEETINGS.

The Mount Pleasant Mining Company, No. 18 Wall street, Room 47, New York City. Annual meeting of stockholders and election of trustees October 3d, at twelve o'clock M.

Wahsatch Iron and Coal Company, No. 42 New street, New York City. Annual meeting of stockholders and election of trustees, October 4th, at half-past three P.M.

DIVIDENDS.

The Mount Pleasant Mining Company, of California, has declared a dividend (No. 3) of fifteen cents per share, payable September 28th.

The Osceola Mining Company, of Michigan, has declared a quarterly dividend of fifty cents a share, payable October 1st.

The Sierra Grande Mining Company, of New Mexico, has declared a dividend (No. 7) of one hundred thousand dollars, or twenty-five cents per share, payable on and after October 3d, to stockholders then of record.

DIVIDENDS PAID BY MINING COMPANIES DURING THE MONTH OF SEPTEMBER, AND FROM JANUARY 1ST, 1883.

PIPE LINE CERTIFICATES.

Messrs. Watson & Gibson report as follows on the petroleum market :

One week ago to-day, the oil market was exceedingly strong, selling up to $1.17¼, with the appearance of going higher. The bulls were triumphant, but their hopes were dashed to the ground on Saturday by the announcement that Howe No. 5 was a large well, that Howe No. 7 was good, and that Porcupine No. 11, which is three quarters of a mile away from frontier developments in Balltown, was in and showing well. This extended the area of productive territory, and under these influences oil sold down to $1.12⅜. A strong effort was made to hold it, otherwise it probably would have declined more. Monday, Porcupine No. 10 came in, and prices remained weak and the market dull. Wednesday, the market was advanced to $1.16½ on the report that Porcupine Nos. 10 and 11, Grandin No. 15, and Howe No. 7, were declining, but yesterday the market gave way to $1.14¼. The fact now appears to be that the statement of development-work, which will be out October 1st, will be bearish, as it will doubtless show that the new wells in September have added more to the production than those of August.

Exports continue rather large, refined oil is firm, and the shipments from the oil regions exceed the "runs" so far this month by over 300,000 barrels. This is bullish, and besides this, the point to buy oil has been industriously circulated during the past few weeks, and the consequence is, the trade here is generally long. The oil regions are more bearish. It is more than probable that oil will sell down to $1.13 or $1.12 before any important advance takes place.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange :

	Opening.	Highest.	Lowest.	Closing.	Sales.
Sept. 22	$1.16	$1.16⅝	$1.13½	$1.14¼	3,797,000
24	1.13⅞	1.14⅝	1.12⅝	1.13¼	2,743,000
25	1.13⅛	1.15⅝	1.13⅛	1.15⅝	3,274,000
26	1.16	1.16½	1.15½	1.15⅝	3,443,000
27	1.15½	1.15½	1.14⅝	1.14⅝	2,241,000
28	1.14⅞	1.15¾	1.14¾	1.15⅝	2,379,000
Total sales					17,877,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, September 27.

There is very little change to note in the market for the past week. Prices are quite firm ; but there is not much doing either in copper or other mining stocks, and the transactions for the whole week would not be more than a fair day's business in active times. In copper stocks, Calumet & Hecla is steadily held at about $245, with only a few shares offered at that price. Franklin continues to improve, and sales are reported at $12, a gain of $¼ from last week. Quincy advanced on the 14th to $55, and was very firm for a few days ; but later, sales were made at $54 ; to-day, $54⅛ was bid, and none offered better than $54¼. Pewabic sold at $3, same as last week, closing $2½ bid, $3 asked. Allouez sold at $1⅛, a decline of 25c. since last sale (August 28th). This comprises all the dealings in copper stocks at the Boston Stock Exchange for the week, showing how little interest is manifested in this class of securities.

In silver stocks, there is even less doing than usual, and prices have a tendency downward. Bonanza declined from $2⅛@$1¾. Catalpa, steady at 35c. Silver Islet, from $3@$2½. Sullivan, to 87½c. At the Mining Exchange, an unusual dullness prevails. Bowman Silver Company declined to 7c. An assessment of 5c. per share has been levied, payable October 1st. Massachusetts & New Mexico, steady at 4@5c. Sullivan has been quite active at this Board at 78@95c., mostly at the latter figure, buyer's option.

3 P.M.—There was no feature to the market this afternoon, and prices remain unchanged.

SAN FRANCISCO MINING STOCK QUOTATIONS.

Daily Range of Prices for the Week.

BULLION MARKET.

NEW YORK, Friday Evening, Sept. 28.

The advance in the London market the past week has improved the rate for silver here, and leaves our market firm at the figures of annexed table :

DATE	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Sept. 22	50 13-16	110¾	Sept. 26	50 15-16	110¾

25	50⅞	110¾	28	50 15-16	110¾

Digitized by Google

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14⅛ per cent, to arrive at actual value.

MINES.	States.	Month of August.	Year from Jan. 1st, 1883.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended September 28th, as compiled from various sources, amounted to $254,111, as against $246,662, reported for the previous week. The receipts from January 1st, 1883, to date are $8,489,047.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended September 22d	$560,723
Corresponding week last year	25,884
Since January 1st, 1883	10,555,789
Corresponding period last year	43,996,801

Imports.

Week ended September 22d	$782,262
Corresponding week last year	40,124
Since January 1st, 1883	11,511,590
Corresponding period last year	2,707,936

Foreign Bank Statements.—The governors of the Bank of England, at their regular weekly meeting, reduced the bank's minimum rate for discount, from 3½ to 3 per cent. During the week, the bank gained £137,000 bullion, and the proportion of its reserve to its liabilities was raised from 46⅝ to 47⅝ per cent, against 39½ per cent at this date last year. September 27th, the bank made a further gain of £280,000 bullion on balance. The weekly statement of the Bank of France shows a gain of 1,225,000 francs gold and a loss of 1,600,000 francs silver.

METALS.

NEW YORK, Friday Evening, Sept. 28.

Copper.—The situation in this metal is practically unchanged. It is firmly held, and inquiries from abroad for small lots can not be filled. A few hundred thousand pounds have been placed at 15¾c. for Lake, and it would be impossible to get any copper for less, though on the other hand it should be noted that there are few buyers. Other kinds remain 14¼@14¾c.

England cables Chili Bars lower, namely, £62 15s. to-day.

Tin.—The arrivals of last week have been pretty well distributed on the trade in jobbing lots, and our market continues firm at 21½c. for spot Straits and Malacca, and 21¼c. for Australian, which is scarce. Banca is quoted 22c. England cables Straits to-day £95 7s. 6d.

Lead.—There has been a sale this week of 200 tons of Nevada lead at 4·30c., under special circumstances, however, as 100 tons of this favorite brand among our smaller consumers brought 4·37½c. Besides this, there have been jobbing sales at 4·32½c. for Common.

Messrs. John Wahl & Co., of St. Louis, wire to us as follows:

The market is a little easier. We quote sales of 600 tons of Refined at 4·03c. The demand is only moderate, and there is but little doing in Common, which we quote nominally 3·97½@4c.

From Chicago, Messrs. Everett & Post send us the following dispatch:

Business has been quiet and transactions limited in amount, with quotations at 4·05, 4·07½, and 4·10c. Buyers are apparently anxious to purchase, but do not want to pay more than the ruling figures. Sales will scarcely foot up to 500 tons.

Spelter.—The market continues firm at 4·45@4·50c.

Antimony.—There has been no change.

IRON MARKET REVIEW.

NEW YORK, Friday Evening, Sept. 28.

American Pig.—The market for pig for foundry purposes has been extremely dull. Makers profess to be unable to go any lower, and if the fall trade goes on at this very unsatisfactory rate, many will probably decide to blow out rather than go on exhausting their ore lands, etc. The blast-furnace men using anthracite as a fuel are very indignant at the fact that they are forced to pay such high prices for fuel. Labor is as low as it should be allowed to go in any case; ore is so cheap that many banks have stopped working; freights on raw material and finished product are a little lower this year than they were; and yet anthracite coal costs the furnacemen as much to-day as it did when iron was selling at $28. Furnacemen in the Lehigh Valley are paying $3.25 for their coal. They claim that, with every item in the cost reduced in some instances to the lowest limit, they are made to suffer from an artificial upholding of the price of coal. Coke is not available to more than a limited extent, the haul being too long from the Connellsville region. They urge that, if they are not assisted by a reasonable reduction in the cost of fuel, they will simply stop.

Transactions during the week have been on a very moderate scale. We quote No. 1 Foundry, $21.50@$23; No. 2, $19@$21, according to quality; and Gray Forge, $18.25@$19.50, all at tide-water. There have been sales of round lots of Bessemer Pig at $20, and Spiegeleisen is quiet at $30.25@$30.50 for 20 per cent. Low grades are dull at $25.

At the Exchange, the following transactions were recorded:

Monday, September 24th, 200 tons pig, No. 1, February, $21.37½; 200 tons carbon pig, No. 1, spot, $20; and Wednesday, 100 tons No. 1, December, sold at $20⅝; 500 tons No. 1, February, sold at $20⅝.

The sale of Carbon at $20 was attended by special circumstances. It was apparently made for effect at the Exchange, after attempts to place it on the trade failed.

Scotch Pig.—There is very little that is new to report. Freights have advanced to 8s. 6d.

We quote ex ship and to arrive: Coltness, $23.25@$23.50; Langloan, $23@$23.50; Summerlee, $22.50@$23; Dallmellington, $20.50@$21; Eglinton, $20@$20.50; and Glengarnock, $22@$22.50.

At the Exchange, the following lower cable quotations were received: Coltness, 57s. 3d.; Langloan, 57s.; Summerlee, 56s.; Gartsherrie, 55s.; Glengarnock, at Ardrossan, 54s.; and Eglinton, at Ardrossan, 47s. 6d.

Rails.—Business is very dull, and a number of the mills have no engagements beyond the first of December. It is likely that the most unfavorably situated will have to stop temporarily, unless orders come forward more liberally, and prices are maintained at the present quotation, $37@$37.50 at mill.

Old Rails.—There is very little doing at lower figures. We quote $22.50@$23 for Ts.

Scrap.—Scrap is dull at $22 ex ship.

Philadelphia. September 27.

Pig-Iron.—Another week has passed with comparatively few large transactions, but the usual number of inquiries. Negotiations which, it was thought, would be brought to a close last week, for large lots of forge iron, are most of them hanging fire, with no immediate probability of their resulting in business. Large transactions could be closed at any time, if brokers or makers would accept the offers in hand. The chief reason why so little is done is, that the demand for finished iron is irregular, and prices are declining. An upward tendency in the finished product or an improved demand will change the entire situation in pig-iron. A careful investigation of mill yards shows stocks generally light, and the same is true of the foundry yards. Eastern consumers are following the same cautious policy, and are waiting more for an upward tendency than for lower prices, which they admit are not likely to be reached. Sales were heard of this week in 100-ton lots at $17.50@$18, at which most of the business is done. Some of the standard brands are held at $18 and $18.50, and the stronger companies are determined to adhere to these prices, whether they sell or not, thinking that an accumulation of stocks will be the safer and wiser plan in the long run. Sales of Foundry have been made in small lots at $21.50 and $22, with an average of $20 for No. 2 Iron.

Foreign Irons.—From 7000 to 8000 tons of Bessemer have sold at $21, and a good deal more could be sold at $20.50. Spiegeleisen is under negotiation at $30@$30.37½, with $30.50 asked. Large sales could be made at $30. A few small lots were heard of at $30.50.

Blooms.—The usual business was done in blooms, and prices show a little weakening from the average quotations of $58 and $48 for charcoal and anthracite. Several bids are in, and buyers think that prices will weaken still further.

Muck Bars.—Muck bars have weakened to $33 in some cases, with $34 asked for the better makes. The demand has been moderate.

Merchant Iron.—The merchant iron market has been rather quiet, and mill owners report indifferent inquiry for delivery after November 1st; but a good deal of iron is contracted for, for delivery during October, and the output will be easily marketed up to the end of that month. Prices for large lots are 2@2·10c.; 2·10@2·20c. is asked for small lots, but the tendency is unfavorable to manufacturers. Common iron has been sold as low as 1·85c., but 1·90@2c. are the average figures.

Nails.—The largest transactions are in car-load lots at about $2.90@$2.70 offered; and with the threatened competition from the West, a downward tendency exists, aided by the falling off of the active demand which lasted all summer. Retail lots sell at $3.10@$3.15 in some cases. Jobbers are not buying heavily, though ready to do so when bottom prices have been reached.

Plate and Tank Iron.—Several inquiries have just come to hand for Plate and Tank for November delivery, and manufacturers are hopeful of obtaining better prices, especially for small lots. Large consumers are disposed to do business, if the desired concessions can be had. Average quotations are 2·40@2·50c. for Common Plate, with Shell, Flange, and Fire-Box at old figures.

Structural Iron.—No special points of interest have been developed this week. The general activity continues, and the negotiations which have been in progress are on the point of closing for heavy lots for delivery in November and December.

Steel Rails.—Quotations are given to-day at $37@$38, but business has been done at less, though particulars are withheld. Sales covering 20,000 tons have been heard of in the Pennsylvania mills in the past week.

Old Material.—$22.50 and $23 have been bid this week and $23.25@$23.50 asked. Bridge rails are quoted at $24. Several thousand tons are wanted.

Wrought Pipes and Tubes.—The demand for wrought pipes and tubes has been inactive this week, and heavier discounts can be had on large lots. Bids for several million pounds of cast pipe were made at 1·53c. per foot for 36-inch piping.

Scrap.—The yard men report moderate activity for the best scrap, and quote $24.50@$25. Inferior stuff is not wanted. Cargo lots, nominally, $23.50.

Pittsburg. September 26.

The depletion in the stocks of pig-iron which has been going on in the mills of the city for several months past has resulted in a movement on the part of consumers to cover for the next sixty to ninety days, and a number of large requirements have already been placed with that view. A number of offers have been made, some of them below current quotations. There is a general disposition to buy more freely, because of the fact that prices have reached the lowest possible limits, and for desirable irons the possibility of an upward tendency is admitted. The local furnaces are producing to full capacity, and are selling stocks as soon as made. Bridge Iron has sold freely at $17.50@$18; Extra Red Short, $19; Bessemer, $21.50; C. B. Charcoal, $32; Muck Bars, $33@$33.50. Offers have been made at $32.50 and $32.75. Bar Iron is held nominally at 2c., but assorted orders have been filled at 1·80c. Shipments have been made to the interior of the State, and sold at 2c. and less. Competition is increasing, and buyers are holding back, expecting that the surplus capacity will result in a still further reduction of prices. Mills working on specialties are coming out even, but the sales of plain bars are almost at cost. The expected restriction in the production of the 2500 nail mills in the West for one month will check the downward tendency which is in progress. Nails have sold under $2.70. Demand is not heavy, owing to this tendency. Wrought Pipes are 75 per cent off list; Tubes, 60 off. Old Rails are offered at $24.50. Offers have been made at $24. Sales are light.

November and December deliveries of steel rails can be had at $38. Inquiries for large lots are still coming to hand, but very little business results. The demand for merchant steel is said to be light, but the mills are working to nearly full capacity. Wrought Scrap is quoted at $21@$22 for Common, and $23 for Best.

COAL TRADE REVIEW.

NEW YORK, Friday Evening, Sept. 28.

Anthracite.

The slight improvement noted in the beginning of this week is showing indications of slackening up a little. The domestic sizes are the most active, as they generally are during this time of the year, and as the larger sizes are broken up to meet the demand, by some of the companies, broken coal, too, is in comparatively light supply and is stiffer. Egg and chestnut, however, are in over-supply. As these are pre-eminently manufacturing sizes, it is evident that they are held at too high a price. The anthracite operators are simply driving the trade into the arms of the bituminous coal miners. So far as our local market is concerned, there is every evidence that it may continue to worry along until the close of navigation puts a stop to shipments by water to many distant points. That our market will be unable to stand up under the flood of coal that will then come to it seems to be generally conceded, and New York interests will then strongly urge a restriction of work.

There has been the usual cry on the part of some for an advance of the circular, but even those who are usually the most urgent among the large companies to call for this quack remedy are not now in favor of it.

The manufacturers of anthracite pig-iron are growling about the high prices of coal which they must pay. They claim that their interests deserve some consideration.

Bituminous.

From Clearfield shippers, comes the usual autumn complaint of scarcity of cars; but with supplies of coal coming from the Cumberland region sufficient to cover current requirements, there seems little prospect of a material advance in prices, which still rule low. The Cumberland companies report an improvement in the demand, probably traceable to the above cause. They have also secured a contract for supplying the Fitchburg Railroad with 15,000 tons of coal.

STATISTICS OF COAL PRODUCTION.

Comparative statement of the production of anthracite coal for the week ended September 22d, and year from January 1st:

TONS OF 2240 LBS.	1883. Week.	1883. Year.	1882. Week.	1882. Year.

SUPPLIES.

CORDAGE.

The manufacturers of cordage have adopted a revised price-list, under date of the 23d inst., showing an advance of ¼ cent per pound on Manila. The following are the present prices, subject to the regular trade discount of 1 cent per pound:

	Cents per pound.
Manila Rope.	
1¼-inch cir. and upward	16
12 thread, or ⅜-inch diameter	16½
6 and 9 thread, or ¼ and 5-16-inch diameter	17
Hay rope, 2, 3, 4, or 5 thread	16
Bolt and point rope	17½
Tarred rope and lath yarn	15½
Stave, leather, and hop twine	16½
Sisal Rope.	
1¼-inch cir. and upward	10½
12 thread, or ⅜-inch diameter	11
6 and 9 thread, or ¼ and 5-16-inch diameter	11½
Hay rope, 2, 3, 4, or 5 thread	10½
Tarred rope and lath yarn	10
Russia Hemp.	
White rope	17
Tarred rope and ratlin	11
Spun yarn	10½
Bolt rope	18
Marline, houseline, rounding, and hambroline	15
Packing	16
American Hemp.	
White rope	18
Tarred rope and ratlin	12½
Spun yarn	12
Lath yarn	12½
Packing	17
Marline, houseline, rounding, and hambroline	16
Sash and bell cord	25@35

FREIGHTS.

Horsford's Acid Phosphate,
For Alcoholism.

DR. C. S. ELLIS, Wabash, Ind., says: "I prescribed it for a man who had used intoxicants to excess for fifteen years, but during the last two years has entirely abstained. He thinks the Acid Phosphate is of much benefit to him."

Advertisers' Index..... xii

THE competition between the Colorado "mountain and valley" smelters is growing more severe, and those in the vicinity of Leadville are one by one ceasing to purchase new supplies of ore. They urge that the present freight on base bullion to Denver, $12 per ton, is too high, compared with the low charges on ore, $5 per ton. The advantages possessed by the works at Pueblo and Denver in the way of cheaper labor and cheaper fuel seem to make the transfer of the bulk of the business to the valley works only a question of time.

THE protracted dullness in pig-iron, at a season which should be one of the busiest of the year, has culminated in an open cut in prices. Our weekly market reports have closely reflected the growing disappointment felt by the trade during the month of September, which no attempts at glossing over could hide. As usual, the managers of the Thomas Iron Company have taken the lead. In the past, their course has been the butt of sharp criticism by other makers, who were doing quietly what Mr. B. G. CLARKE was doing openly. The experience during the past year has proved the wisdom of this course, and the trade now generally acknowledges it. The temptation is great on the part to furnace-men to pile up iron, in order to avoid the cost of blowing out, and the future expenditure of blowing in again. This protracts the period of depression and makes a crisis, when it does come, all the more disastrous. Prompt reductions, openly made, give confidence to the buyer and precipitate a remedy by forcing the weaker producers to stop.

A VERY serious accident occurred during the meeting of the Iron and Steel Institute at Middlesborough, which painfully illustrates the danger incident to the visit of a large number of persons to industrial establishments. A number of members of the Institute visited the Northeastern Steel-Works before the time appointed for their reception. When on the platform, on a level with the cupola top, one of the ladle-buggies filled with molten metal stuck fast as it was pushed by a locomotive. The engineer backed up and tried to force the buggy over the obstruction by running against it. The shock broke the clutch, and the ladder began to swing around, slowly emptying its contents on the platform in the direction in which the visitors and a number of men were standing. All of them were covered with a spray of molten metal, a number were more or less injured, and one gentleman, Mr. SAMUEL DAVISON, of the Horbury Bridge Iron-Works, near Wakefield, was so seriously burnt that he expired a few hours afterward. While none of the visitors was directly responsible for the accident, their presence possibly might have had something to do with it indirectly. It is certain that, in a mill, the visit by a large number of strangers increases the danger of accidents. Often, unconsciously and unintentionally, they stand in the way of the men, whose attention is only too often diverted from their work, and who frequently take extra risks in order to make a special show of activity. We have repeatedly observed instances, too, where the visitors unconsciously, placed themselves in positions of danger. The gentlemen who act as guides to their visitors can not watch personally over the safety of all, especially as there are generally, in every party of the kind, a number of persons who prefer to ramble off by themselves.

THE UTILIZATION OF THE WASTE PRODUCTS IN COKING.

Probably no subject affecting alike the coal and iron interests has deservedly attracted so much attention as the utilization of the waste products in coking. The developments during the current year have advanced the question far beyond the preliminary stage when the principal amount of work done is to compile appalling figures of the loss to nations by the failure or neglect of their coke-makers to gather the oil, tar, and ammonia escaping in the gases issuing from their ovens. It is now generally admitted that "there is something in it," and all efforts are now directed to ascertaining how much. When, some time since, we presented to our readers the leading designs now before the technical public, we repeatedly had occasion to remark how comparatively meager were the actual figures of results obtained on a working scale, and how striking was the absence of trustworthy testimony on some vital points. The accumulation of experience on such a subject is, of course, slow, but the facts brought out at the Middlesborough meeting of the Iron and Steel Institute prove that those engaged in working out this important subject can not be accused of inactivity. Two papers were read before the society, one by Mr. ROBERT DIXON, of Peases's West, Darlington, on the Simon-Carvès ovens, and a second by Mr. J. JAMESON, of Newcastle-upon-Tyne, on his plan. Both gave the results of actual working and both were subjected to a close criticism, in a long and animated discussion, in which many points of interest were brought out. Together, papers and discussion would fill an entire issue of the ENGINEERING AND MINING JOURNAL, and we must therefore content ourselves with a summary of the evidence presented.

Turning first to the working results of the Simon-Carvès system at Peases's West, with a coke plant of 25 ovens, Mr. DIXON reports that in 215 working days they coked 7042 tons of coal, produced 5424 tons of coke, a yield of 77·03 per cent, and furnished 43,164 gallons of tar and 195,076 gallons of ammoniacal liquor, or 6·12 gallons of tar and 27·70 gallons of liquor, from 6 to 7 degrees Twaddell, per ton of coal. Against a claimed increase of 15 per cent in the yield of coke over bee-hive ovens and the value of the by-products, stands an extra cost for labor, inclusive of that of collecting the latter, of 1s. 3·31d. per ton of coke, the total cost being 2s. 3·96d. per ton. The average value of the tar and the ammoniacal liquor is placed at 3d. and 1d., respectively, per ton, making the returns from this source £1351.

The Jameson system has been only used on an experimental scale apparently, at Bell Brothers Page Bank colliery at Fellwig, and at the Weardah Iron and Coal Company's colliery at Tudhoe Grange. It will be remembered that it is merely a modification of the ordinary bee-hive oven. The most efficient plant is that at Fellwig, where the coal that yielded at its best 5·12 gallons of oil and 1 pound of ammonia per ton of coke gave on an average 5·63 gallons of oil and 3·16 pounds of ammonia, the yield of coke being 67·5 and 68·5 per cent in both cases, in excess of the returns from ovens before being converted into the Jameson type.

Digitized by Google

Mr. JAMESON estimates the profits from a plant of 100 ovens, coking 1100 tons of coal per week, and yielding 5 gallons of oil per ton at 2½d., and 3 pounds of sulphate of ammonia, valued at 13s. per cwt., at £3536 per annum, on an outlay for the conversion of 100 ovens of £1750. It will be noticed that while, in the former system, the aim is to make tar, the object of those working the latter is to produce oils.

The Simon-Carvès ovens labor under the disadvantage of being more costly, the actual outlay for the first battery of twenty-five being £226 per oven, which would probably be reduced to £180 in building a set of 100 ovens. The capital required for putting up twenty-five 11-foot ordinary bee-hive ovens is stated to be £58 per oven, while the cost of converting the latter into Jameson ovens is given as from £17 to £18 per oven. Other things being equal, the Jameson oven, or the earlier Aitken oven, differing from it only in certain details, would have by far the advantage. So far as the values of the by-products are concerned, they are not directly comparable, because of the difference in the character of one of them and the absence of a definite statement in the case of the Simon-Carvès oven concerning the amount of ammonia in the liquor.

Turning to the experience had in working the different ovens, it is reported that, in the Simon-Carvès system, there in the danger of pitch collecting in the gas mains, which Mr. DIXON claims to have overcome. It is proposed to heat the air for burning the gas for coking in a "recuperator," fired with the waste gas after the extraction of the liquid by-products. This system, by increasing the temperature of coking, will, it is argued, make the yield of coke larger still, and reduce the time of coking from 72 to 48 hours. It is now in use at Bessèges, at the coke-works of the Terre Noire Company. It was found, too, that the form of the floor of the Simon-Carvès oven was not adapted to Durham coal, and a new plant at the Peases's West works will be modified in this respect.

The Jameson system has also had its troubles, some of which appear to be inherent in the design. Mr. JAMESON extracts the gases from the distillation of the coal by applying suction at the bottom of the charge. He himself says:

"It is clearly possible by excessive suction to diminish the yield of coke by driving air through the charge and so burning it; and it is as clearly possible by too slight suction to make a recovery of products of almost no value; but the range between these limits is very wide, and by due proportioning of the suction in reference to the circumstances of the case, it is possible to effect a large recovery of oil and ammonia, with a full yield of coke of the highest quality. In this regulation of suction lies the whole secret of the success of the process; and doubtless, to insufficient attention to this point are due in large measure the varying results which have occasionally been obtained.

"Sometimes differences in yield of products are observed with the same coal in different ovens, and sometimes even with the same coal in the same oven; and it may be regarded as the one essential requisite to obtain the best results, that the process be conducted (in regard to the amount of suction) alike in accordance with the quantity of coal treated, the peculiar character of the coal, the progress of ignition, the shape of the oven, the amount of chimney draught pulling in the opposite direction when the oven is more or less closed, and perhaps other circumstances as well.

"The necessity for the observance of the conditions last named will be apparent at a glance. In regard to the quantity of coal contained in the oven, and its depth and the progress of ignition, it is manifest that under various and varying circumstances a mass of closely packed coal is interposed between the measured suction in the oven bottom and the stratum of coal in which the gas is forming, and that, to produce an equal suction at this point, the applied suction outside should vary in the ratio of the resistance of the interposed mass of coal. The character of the coal and its condition, whether ground or otherwise, also of course affects this, and the chimney draught is of much importance. In regard to the latter, there can be no doubt that at the early stages of the coking operation, while there is access of air over the charge, the actual suction due to the chimney is diminished by that access of air; but when the oven is nearly or entirely closed, the pull of the chimney is thereby increased, and therefore increased suction externally is required to produce an equal effect. With a single oven, worked by a blower of its own, it is of course easy to regulate the suction as may be desired; but with a range of ovens exhausted through one main pipe, it has not been found easy. In order to avoid suction much in excess of the requirements in some ovens in a range, it has been usual to fix the suction for the whole range at much less than would be advantageous for other ovens, and to work at a mean, which thus sacrifices efficiency in two ways. Another disadvantage to the process has arisen from the fact that, even if the speed of the blower be kept uniform (which is not always practicable), the shutting off more or less of any ovens connected with it, which may have become coked throughout, causes a variation in the pull by the blower, and the coke-maker, with this in view, usually errs upon the side of too little suction. To obviate the difficulty stated, it was proposed to work ranges of ovens with several main pipes exhausted to different degrees, and to one or other of which each oven could be connected in turn through a sluice-valve, so as to give different suction at stated times during the progress of the coking; but the increased expense involved has prevented the application of this plan. By a recent improvement, however, the suction of the blower has been made uniform automatically, independently (within limits) both of the speed of revolution and the number of ovens connected to it; and with a single range of pipes, the suction to each oven can now be varied and adjusted as efficiently and as simply as if several ranges of pipes were used."

It appears, from remarks made by Mr. JAMESON during the discussion, that this improvement consists merely in providing the suction pipes of every oven with valves, the suction being diminished gradually as the process of coking continued toward its end.

The evidence is conflicting on the principal point, so far as American coke-makers and iron-masters are concerned, the question whether the quality of the coke made in ovens from which the products of distillation are gathered suffers. As to the increase in the yield claimed by the Simon-Carvès oven, as by all ovens of the Belgian type, there is some doubt, as the amount of water in the coke was not given, though stated to be about the same as in the coal from which it had been made. The coke from the Simon-Carvès ovens is conceded to be dense and heavy, without the strong luster of the product of the ordinary bee-hive. Experience in this country, at least so far as it refers to the Connellsville coal, is against the Belgian oven, so far as iron smelting is concerned. There seems little doubt that this inferiority, which is certainly not imaginary, depends entirely upon the structure of the coke. Mr. G. E. STEAD, of Middlesborough, the well-known metallurgical chemist, stated, in the discussion following the papers, that he had tested chemically, the coke made in the bee-hive and in the Simon-Carvès ovens, to see whether there was not a greater proportion of volatile hydrocarbons left in the coke from the latter. He reports that the difference was extremely small, being about one per cent in the latter to from one half to three quarters of one per cent in the former. From a chemical point of view, he therefore declared them practically the same. The burden of proof lies with the makers of the denser fuel. If they can show that, other things being equal, the dense fuel will do as good work in the blast-furnace as the standard product of the bee-hive, the Simon-Carvès and other ovens of that type will receive recognition in the great Durham District in England, as well as in the Connellsville region in this country. Mr. THOMPSON, the manager of Bell Brothers, Clarence Works, spoke in the most emphatic way against it. He stated that he had used 300 tons of the Simon-Carvès coke, and although he started by reducing his burden by 5 per cent, the grade went down to Forge 4, and he came to the conclusion that, if they had gone on another week with the same fuel, there would have been a difference of 12 per cent to get the same quality of pig which they were producing before using it. The maker of the coke, Mr. DAVID DALE, on the other hand, explained that the fuel used during the experiment at the Clarence Works had been exposed to snow and sleet for a long time, and that it was therefore exceptionally wet. At the works of the president of the Institute, Mr. B. SAMUELSON, the new coke did as well as bee-hive coke.

The coke from the Jameson oven is generally conceded to be the same in appearance, and in the furnace it proved to work as well as ordinary bee-hive coke. Thus far, we can not escape the conclusion that the Simon-Carvès oven labors under the disadvantage of producing a fuel that is not as well adapted to the blast-furnace process, ton for ton, as the bee-hive coke. Whether the increased yield, due allowance being made for any larger quantity of water in it, will fully or more than compensate for any decrease of efficiency due to its structure, remains to be seen. It is certain that the Jameson and Aitken systems, with their slight outlay for alterations of existing plant, and with the absence of any appreciably injurious effect upon the quality of the fuel, will be more attractive to American coke producers and more acceptable to our iron-masters.

Here it may be well to call the attention of English metallurgists to a paper read by Mr. F. P. DEWEY, of Washington, before the American Institute of Mining Engineers, in which he gives his methods for determining the porosity and specific gravity of coke, and the results of a series of tests on cokes from Connellsville, West Virginia, Tennessee, Colorado, and Ohio.

The Debris Controversy Boiled Down.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Woodruff *vs.* North Bloomfield Mining Company *et al.* is the title of a case pending in the Circuit Court of the United States for this State, which involves the right to mine by any method, although the defendants are sued as hydraulic miners. As it affects the prosperity of thousands of people and the value of many million dollars' worth of property, I shall endeavor to present impartially both sides of the controversy, and for convenience will suppose both parties presenting their case.

Plaintiff (representing the owners of lands and town lots near the valley-rivers): You are pursuing an unlawful occupation, whereby you have covered with mining *débris* thousands of acres of productive lands, and threaten destruction and damage to other lands, and to structures erected in towns, the safety of which is imperiled by your operations. You are filling the navigable streams of the Sacramento Valley with sediment, impeding navigation and causing us great expense in the erection and maintenance of levees for protection from the floods which result from the filling of the rivers during periods of high water; and you are injuring the bay of San Francisco. The continuance of your operations will be detrimental to the best interests of the people of the State, and fatal to the prosperity of hundreds of farmers owning lands near the valley-rivers. Your business is a public nuisance, and we ask that you be perpetually enjoined from the further use of water as an agency in removing dirt, and from the sale of water to others for such a purpose.

Defendant (representing the mining interest): We are engaged in a legitimate and lawful business, sanctioned by special laws of the United States, and by custom and usage for more than thirty years, whereby we have acquired an easement and prescriptive right. We have purchased our lands from the United States government as mineral lands, and paid for them double the price of agricultural lands, with the full knowledge on the part of the government of the method to be pursued in extracting the gold, as is apparent by the inspection of the heading and vignettes of United States mineral patents, representing hydraulic mining as at pres-

Digitized by Google

ent prosecuted. Confiding in the validity of our title and easement or franchise, we have expended many millions of dollars in driving long tunnels to tap our auriferous deposits, and in building reservoirs and digging canals to convey water to our mineral lands. In the prosecution of these works, populous communities have grown up; and thousands are dependent upon our industry. We have added to the metallic wealth of the world nearly 1200 millions of dollars, and, if undisturbed, will continue to add thereto at the average rate of $18,000,000 per annum for an indefinite period, estimated at not less than one hundred years. Gold is the great lubricator of commerce. In the present age of progress, it purchases all necessaries; and the nation which produces it can want for nothing. Our country is the great storehouse of gold; our auriferous ancient rivers are the only known large deposits of the metal, and these mines are the only available source of large production. The equities of our tenure of lands and public policy alike forbid suppression of our business. The breaking down of dirt by projected water is an incident of our business, without which it can not be pursued. The mountain cañons are the natural receptacle of the material washed from the mines. In them, the heavier or coarser matter becomes impacted near the mines, the lighter going gradually downward, but susceptible of being restrained by dams. You have endangered your towns in periods of high water by a defective and unscientific system of levees, and you have obstructed the efforts of the government to protect the navigable rivers by measures recommended by government engineers. The bay or harbor of San Francisco has in no manner been affected by our operations. We ask that your bill be dismissed.

The above is substantially the case to be presented to the Circuit Court of the United States, and thence appealed to the Supreme Court; for it is admitted that the losing party will carry the case to the final court. The taking of the testimony had been in progress on September 1st more than ninety days, during which some 210 witnesses had been examined. The testimony so far covers more than 20,000 pages of two hundred and fifty words each.

JUSTITIA.

SAN FRANCISCO, Sept. 20.

REMARKS ABOUT LEAD-SILVER BULLION SMELTING IN THE WEST.

Written for the Engineering and Mining Journal by Carl Henrich.

The object of lead-silver bullion smelting in the West is the extraction of lead and silver combined from the argentiferous lead and dry ores. The lead takes the same *rôle* in smelting which the mercury takes in the amalgamation or "stamp-mill" process, only that the lead is generally not used in its metallic state, but in the form of its various ores. Sometimes metallic lead in the form of base bullion has been used, when lead ores were scarce; but doing this has proved faulty, a large loss of lead and silver being the invariable result. Lead-silver smelting consists in the proper mixing of the different argentiferous lead and dry ores, the addition of the necessary fluxes, and the smelting of all this in the proper furnaces with the proper fuel.

There may be some hearths or reverberatories in the West for lead-silver smelting. If there are, I do not know of them, and can not say any thing about them. I shall restrict my remarks to the smelting in blast-furnaces, and shall consider the best smelting mixture to be made under different conditions, the best style of furnace adapted to the smelting of the charges, the quantity and quality of the fuel to be used, the best and most serviceable fluxes, the blast-pressure and amount of blast employed for the different fuels and furnaces, the impurities of the ores and their treatment, and the flue-dust and its treatment.

In making these remarks, I shall simply give the results of my experience and experiments in smelting, together with some conclusions I have arrived at, but without going too much into details. I shall not advance any theories, except those which I have actually tested and found to work correctly in practice.

In making a charge, that is, the right mixture of ore and flux, we want a certain per cent of lead as a minimum in the charge. With pure ores, containing no zinc, arsenic, or antimony, we may go as low as 8 per cent of lead in the charge; while with ores containing the above impurities in appreciable quantities, the percentage of lead in the charge should not be less than 14 per cent. Then, if not absolutely forced to do so, we should not make a higher grade bullion than one containing one per cent silver, or about 300 ounces to the ton. Higher grade bullion will lead to larger losses of silver, while, with not over half of one per cent silver, or 145 ounces to the ton, in the resulting bullion, the results in good smelting will agree very closely with the assay results of the ores, and with good and pure ores will even surpass the assay results of the ore a trifle. With these considerations, it remains for us to find a mixture of these different ores which will require as little flux as possible, a mixture which will flux itself, if possible. It has been the general custom of metallurgists in the West to find some slag which would work well in their furnace, and to adjust the mixture of the ores and fluxes to the requirements of this slag. This method is a very convenient one, and will, as a rule, give good results so far as making a slag free from lead and silver is concerned. Whether this method is always conducive to the best or even to good financial results, is another and altogether different question.

Slags are silicates, and it is unnecessary here to explain the difference and the characteristics of sub-silicates, singulo-silicates, and bisilicates. It is sufficient to point out the fact that singulo-silicates contain twice as much, and bisilicates four times as much silica to the same amount of bases as the sub-silicates. It is claimed almost universally that a singulo-silicate as slag is an essential factor in good lead smelting. And it has further been claimed that, of all singulo-silicates, that one will be the best in which the ratio of ferrous oxide (FeO) to calcic oxide (CaO) is approximatively as 2 : 1, or as

$$6FeO : 4CaO.$$

In smelting pure ores, containing no undesirable ingredients, such as arsenic, antimony, or zinc, there is no doubt that such a slag will give splendid metallurgical results, especially if the precaution is observed to keep the percentage of silica a little higher than the bases would strictly need to form a singulo-silicate. This slag is easily fusible, requires little fuel and blast, and, with good ores, will keep the furnace open. But from an economical stand-point, it is, even with good ores, not always desirable to make this slag. In case we have to deal, as is frequently the case, with very siliceous ores and siliceous iron and lime fluxes, an attempt to make this slag would often result in using a disproportionate amount of flux, in lowering the lead contents of the charge below the desirable minimum, and in making smelting an altogether unprofitable business.

Now the question arises: Is it necessary in lead smelting to make a singulo-silicate slag? I answer No; we can obtain just as good metallurgical results and just as clean slags by making higher siliceous slags—slags forming mixtures of singulo and bisilicates, or being even true bi-silicates, if we only construct the right furnaces to do it in, use the proper fuel and blast, and do not attempt to make a bisilicate slag in furnaces constructed for the formation of a singulo-silicate slag. Bisilicate slags, or slags which are a mixture of bisilicate and singulo-silicate, demand a higher furnace and a higher temperature in the smelting zone of the furnace, without necessarily requiring a larger amount of fuel. The making of such higher grade silicate enables us to smelt profitably ore mixtures which we should be totally unable to smelt if we attempted to make singulo-silicate slag.

The temperature at which a slag forms or smelts will be the approximate temperature of the smelting zone of the furnace in which the slag is made. This is obvious. No matter how high a temperature we might be able to get by using a certain kind of fuel and pressure of blast, as soon as the temperature rises to the point at which the slag is formed, this slag will run down in liquid form in the space of the furnace (from 11 to 13 inches high) between the lead-bath of the crucible and the tuyeres, and colder yet unmolten material will take its place. No matter, as a rule, whether other products of a furnace, like matte, speiss, even metallic iron, have different formation or smelting temperatures, their temperatures will very soon be either raised or lowered to the neighborhood of the temperature of the liquid slag, because the slag forms as a rule by far the larger bulk of the molten products of the furnace. The temperature at which a slag first forms, I have no doubt, is higher than the temperature at which the already formed slag will be remelted.

This fact that the formation temperature of the slag is also the approximate temperature of the furnace, above which temperature no increase in the fuel or blast-pressure will be able to raise it, has not received enough consideration in ore smelting. Most speisses, for instance, require for their fusion a higher temperature than that of the commonly made singulo-silicate slags. "Hinc illæ lacrimæ"—therefore these speiss-sows.

Unfortunately, we have very few reliable statements of the different temperatures necessary to the formation and melting of the different silicates and other furnace products. But we do know that higher slags containing percentages of silica, as a rule, are hotter than the singulo-silicate slags. It will be desirable and advisable on this account to make a higher silicate, when we have to deal with an ore-forming speiss.

What kind of slag to make will depend on local circumstances and on calculations and experiments in each separate case. It will be a severe test and show the ability of the metallurgist, to make the right slag in the right place, and not try to make one so-called standard slag do the work in all cases, and say where this slag will not work lead smelting will be a failure. If the furnaces commonly built at present will not do for the slag which he will have to make, then, to achieve success, the metallurgist ought to be able to design and build a furnace which will do the work. One great factor of success in smelting is, to use as little flux with the ores as possible. This will also reduce the cost of fuel necessary for smelting the same amount of ore. It generally costs more to smelt a ton of flux than it costs to smelt a ton of ore.

The form of the blast-furnace used in lead-silver smelting ought to depend upon the quantity of ore to be treated and upon the nature of the most desirable and profitable slag to be made. For smelting small quantities of ore, the circular water-jacket furnace of not over 66 inches diameter will be the most convenient, and as good as any. A furnace designed for more siliceous ores and slag might have a diameter of 42 inches; but even with 2½-inch mercury pressure of blast, I should not advise any further increase in diameter, as the blast will then not reach the center of the furnace in a sufficiently effective manner. Furnaces for larger consumption of ore ought to be made oblong, with the tuyeres at the long sides, and of a width of from 32 to 36 inches at the tuyeres. I should prefer 32 inches for furnaces not over 11 feet high above the tuyeres. The length varies with the amount of ore to be put through a furnace. The amount of charge smelted with 2-inch blast pressure, coke, and ten 3-inch tuyeres will constitute as much as a single set of furnace hands will be able to handle with twelve-hour shifts. The hight of the furnace is determined by the rule to keep the mouth of the furnace cool. Therefore, if we smelt with a higher blast pressure, we want to increase the hight of the furnace, else we shall get the mouth of the furnace blazing; and this will lead to a great loss in lead and silver by volatilization, which forms the kind of flue-dust hardest to condense.

More siliceous slags will require a higher furnace. The general hight at present is from 10 to 12 feet from the tuyeres to the feed-door. For siliceous ores, the hight ought to range from 14 to 18 and 20 feet. Every blast-furnace ought to be provided with a proper dust-chamber, or at least with a flue leading to a common chamber, where many furnaces are used. According to the experiments made at Ems, and described by Professor Egleston, as much surface as possible ought to be given in these dust-chambers, which may be done in a comparatively limited space by hanging in numerous sheets of iron in a vertical position.

The best fuel, and almost the only one fit to use in the West, is coke. Charcoal made from the local light woods, as pine, aspen, or cottonwood, is hardly worth putting into the furnace, and is doubtless put into many furnaces more from old prejudice than for any real benefit which the furnace derives from it. The pifion charcoal is good, if it can be got burnt thoroughly, which generally is not the case, a large amount of bitumen being kept back in it. Mesquite wood makes a splendid charcoal, but is hard to get in large enough pieces. Fine charcoal is not worth any thing for smelting, and it is of more benefit to the furnace to keep it out than to put it in. It will be found best generally to smelt with coke alone, using only very little, and only good charcoal as a sprinkling along the walls of the furnace. Good fuel ought to carry from 7 to 9 times its weight of charge. At least, I have found no difficulty in smelting with this amount of fuel even very refractory ores. This would

Digitized by Google

be from 11 to 14 per cent of fuel. Fourteen per cent of good fuel, like coke (Trinidad or El Moro with 22 per cent ash), ought to be enough for any charge, after deducting the lead contained in the charge from the weight of it. For instance, if we have a charge of 1200 pounds with 150 pounds lead contained therein: $(1200 - 150) \times \cdot 14 = 147$ pounds of good fuel = 130 pounds coke and 17 pounds good charcoal, which ought to be sufficient for smelting that charge. Where good charcoal as described above (pifion or mesquite) can not be got, it will be best to use coke alone. Of course, there may be places where neither good charcoal nor coke can be had. The best thing to do in such an emergency will be to try quite low and small furnaces, in which the weight will not be very heavy on the soft coal. It will be at least a very unsatisfactory and primitive smelting, and the waste products will afterward form the basis of renewed metallurgical treatment.

The blast will vary according to the kind of fuel used and the hight of the furnace, and it will be a safe rule to give as much blast as possible without getting the top or mouth of the furnace in a blaze. The blast generally used at present varies from half an inch to 1¾ inches mercury.

The impurities most frequently met with in the ores are zinc, arsenic, and antimony. About the proper treatment of zinciferous lead ores, I have almost nothing to say. I have never had any trouble on account of the zinc, but I have never smelted charges with more than 5 per cent of zinc in the charge. I smelted such charges with coke alone, and with a slag between a singulo and bisilicate, the ratio of oxygen being as 4 : 3 and 3 : 2. The only difficulty which showed itself was a rapidly growing accretion at the upper walls of the furnace, diminishing seriously the clear section for the passage of the charges. At first, I thought this accretion to consist mainly of zinc oxide and sulphide, but I found it afterward to be nearly pure artificial galena, with only about 2 per cent of zinc. But I always noticed a faster growth of these accretions during the presence of zinc ore in the furnace. The slag only contained traces of zinc, and most of the zinc doubtless went up the chimney, as the bluish-white zinc color of the smoke showed. With the zinc went also considerable silver.

Arsenic and antimony in the ore will go partially into the bullion, to which they give a very white and clean appearance, easily recognized. But the largest part of the arsenic and the antimony combine with iron and form speiss varying in composition. I always allow one and a half parts of iron to one part of arsenic, which would correspond to Fe_4As. I do not find any difficulty in keeping the furnace clear of speiss-sows, by simply maintaining a hot temperature in the furnace, which can only be done by making a slag which requires for its formation a higher heat.

Formerly in Leadville, I endeavored, like most other smelters, to make a singulo-silicate slag, and with this slag, as soon as I got arsenious ores, I was sure to get a speiss-crust in the furnace. This crust, however thin at first, cooled the lead in the crucible, as it kept it from contact with the hot slag, and the speiss-crust grew gradually thicker, until it grew into a formidable sow and necessitated the blowing out of the furnace.

Acting on the prescription of metallurgical hand-books, that the speisses of the composition Fe_4As, Fe_6As, Fe_7As, etc., were more easily fusible than those containing less iron, I applied, like others, metallic iron, especially old castings, as a remedy. The iron melted down well, but I never succeeded in removing a speiss-crust by these means, and I have yet to learn of the first speiss-sow removed in that way. I have for this reason grown skeptical in regard to the easier fusing of these more ferrugineous speisses. The only safe way to deal with speisses in the blast-furnace, according to my experience, is to keep the furnace hotter than a singulo silicate slag will make it. As speisses carry away considerable silver and gold, it will be prudent to make as little speiss as possible, that is, to use for one part of arsenic as little iron as possible. The speiss Fe_4As will be found to work very well with a slag of the oxygen ratios 4 : 3 or 3 : 2, the latter if there is a large amount of speiss forming in the furnace.

It has been almost everywhere the custom to mix the flue-dust with burnt lime and water to a kind of mortar. This was left to harden in the air, either in heaps or in the form of bricks. This is a very unsatisfactory proceeding, as, when put in the furnace, this mass almost immediately crumbles to a fine powder, only to be, to a large percentage, converted again into flue-dust and part of it probably blown out through the chimney. As this flue-dust contains a large amount of fine coal and bitumen, and as, besides this coal, there will be found in it a large amount of arsenic, antimony, zinc, and other undesirable volatile substances, it might be a good plan to burn a large pile of it over, and possibly thereby sinter the dust together, besides getting rid of some undesirable elements in it. If burning over will not sinter the dust enough to use it in the furnace, it ought to be slagged in a reverberatory furnace, either by itself, or together, with some suitable flux (powdered lead-slag, for instance), before it is put into the furnace again.

A proper regard to all these different considerations is necessary to a successful smelting of lead-silver bullion in the West. The one factor, however, on which financial success mainly depends is to smelt any different given ore mixture with as small a quantity of flux as possible. Doing this, we shall lower the cost of treatment of the ores; for by diminishing the flux used, we shall increase the ore used at the same time. In this way, we shall expend less labor, less flux, and less fuel—the three main items of expense—on each single ton of ore. But we can only use a minimum of flux, if, instead of adjusting our smelting mixture to our slag, as is mostly done now, we adjust the slag we want to make to the requirements of the ore mixture which we have to smelt. To show that we are able to do this was the object of the above remarks. It may be more convenient to follow the first method. It will be surely more profitable, and also metallurgically more correct, to follow the second method.

DENVER, COLO., Sept. 11.

IRON WATCHES.—Messrs. Crowther Brothers & Co., of Kidderminster, in order to prove the malleability and ductility of their iron, have constructed a watch entirely of iron, which keeps excellent time. Claudius Saunier, on reporting this fact in the *Revue Chronométrique*, adds: There is nothing new under the sun. We have a watch upon which is engraved the date of 1504, and in which all the wheels and pinions are made of iron.

A LETTER FROM MEXICO—EL PASO.

Special Correspondence of the Engineering and Mining Journal.

The seeker after mines in Mexico, if he does not always find what he is looking for, is at any rate rewarded by a taste of travel so altogether novel that he suffers less disappointment than he does when returning with an empty game-bag from a fruitless hunt in our own West. The railroads now building will soon put the principal cities north of the capital within rapid reach of one another; but even when they are completed, saddle-horses and pack-train will still be indispensable to reach most off-lying localities. The two principal cities in North Central Mexico are Chihuahua and Durango, capitals of adjacent States; and yet there is no public vehicle plying between them. The Central Railroad will next year supply a passage, but meanwhile a composite mode of conveyance must be resorted to by rail to Jimenes, by coach to Parral, and by private ambulance or horseback to destination, unless a conveyance can be found in Jimenes for Durango directly. Such being the absence of facilities now between two such important centers, it is certain that for many a day, even after the impulse of railroads has been felt, conveyance by quadruped will still be the only one available.

Some hints therefore on the subject of travel may not be amiss. When a journey can be completed by coach, by all means take the coach. It is not more uncomfortable than the average Concord coach, which at best is designed, one would think, by builders who had never seen a human being, so utterly unconformable are all the curves to the curves of our bodies. The clumsy vehicle is drawn by a cavalcade of horses, mules, or donkeys, strung together by dilapidated harness, itself being hung together by raw-hide. The stages are unconscionably long, being from 30 to 60 miles; yet these unfortunate little rats reach the end of their journey by dint of blows, stones, and perpetual haranguing on the part of driver and whipper-up, aided, likewise, by a peculiar but very efficacious plan of shuffling the whole team when it becomes very tired, and turning it out to graze when it becomes hopelessly exhausted. A stage journey begins but does not always end on schedule time. It, however, is well for the traveler and prospective miner to learn at the outset that our maxim about never putting off till to-morrow what can be done to-day, is reversed in Mexican practice, and that nothing is ever done to-day which can, on any plea, be deferred till to-morrow, or, better still, the day after. But, as I have already hinted, stage routes are few, and you have generally to provide conveyance for yourself. If there be a carriage-road to your destination, you may be able to hire an ambulance; but if your journey is to be long, it is better to buy a vehicle and mules, and trust to selling your outfit at your journey's end. For instance, if going from Parral to Durango, you are advised by printed placards in Chihuahua and elsewhere that Ruperto Enriquez runs what the pictures at the head lead you to suppose are coaches from and to all principal points. But the most inquisitive inquiry failed to ascertain even where Enriquez's headquarters were—a fact the posters omitted to mention. Both in Parral and Jimenes, after wearisome delay, a wagon can be hired to deliver you in Durango, 200 miles due south, but nearly 300 miles following the road by way of Mapimi, for about $100 and in about ten days' time. If returning at once, no charge will be made for carrying you back to Parral. Many important points, even outside of the Sierra Madre, can, however, be reached by trail only. The equipments for a horseback journey should be purchased in the nearest large city to destination, even when a coach-road permits of the use of a conveyance for part of the journey; for though Mexico is the home of horses, mules, and donkeys, the chances are many to one against your being able to buy or borrow an animal of any kind in a small mining town or at a *hacienda*. And in making your time calculations, allow a wide margin for loss while negotiating for the purchase of horses and equipments. First you must find a *mosso*, and if he succeed in finding *one* horse a day, he does well; and while doing that, his limited power of combination probably prevents his finding saddles, pack-saddles, saddle-cloths, etc.; therefore more days pass in collecting these. Then the horses have to be shod and provisions collected, all which eats up more time and more money; for the Mexican, once engaged, keeps strict count of his wages.

The subject of provisioning is there and everywhere one of moment. Even if journeying through a settled country, do not count on supplying all your wants by the way. It often happens that even at a populous *hacienda*, especially if the family be absent, you can not buy an egg, a chicken, or a pound of butter or meat. All you can be sure of finding are onions and *tortillas*, thin cakes of unleavened bread, made of corn-meal, previously steeped in lime-water. Some fastidious stomachs resent the infliction of such food; and therefore it is well to take either flour or cabin biscuits. Wheaten flour, but unbolted, can generally be had at the large *haciendas* and country villages; but it is unsafe to rely on getting fine flour except in the large towns. Bacon and canned meats must be taken from the States; for untainted bacon is almost unprocurable in a provincial town, and canned meats are costly beyond the limits of the longest purse. A two-pound can of tongue in Parral was offered as a bargain at a heavy discount at $3.50. Bacon should not be omitted from the stores. It is unnecessary to say that it contains the maximum of nourishment in the minimum of space, and can be substituted almost always for the lard which otherwise enters as invariably and repulsively as the dirt into your *mosso's* cooking.

A good *mosso* is an indispensable requisite, especially to those unacquainted with the language and the habits of the country. It is not customary for a householder, male or female, to do his own marketing. This always falls within the province of a confidential servant; and travelers therefore intrust all purchases to their *mosso*. Silver money sufficient must be taken, and this it is well to distribute in belts or wrapped in girdles to the different members of the party, and to dole it out a few dollars at a time to the *mosso*, who should be required frequently to render a strict account of his stewardship. Reading and writing in that class are much more frequent than is supposed. Your *mosso*, with the assistance of a boy, attends to the horses, keeps the commissariat supplied, cooks, prepares camp, and generally combines in his single person the functions of all the offices of a household, from the scullery boy to the valet. He usually provides his own horse, and receives $1.50 per day, and provisions and provender.

As the baggage has to be packed, it should include no cumbrous pieces

Digitized by Google

but should include plenty of blankets; for on the central plateau—except during the heat of summer, before the rainy season sets in, and often even then—the nights are cold. A pillow makes the head more comfortable than a portmanteau, and it should be provided. Warm clothing may be needed at any time—even a heavy overcoat being a comfort sometimes in the month of July. Buckskin trousers and jacket are made very reasonably in Chihuahua, and make a fitting riding-suit, except in wet weather, the jacket being tailless and the trousers not given to wrinkling. But no trousers, however faultless in fit, will make an ill-shaped saddle any thing but an instrument of torture. However suitable a good Mexican saddle may be for a long journey made at a slow speed—most of them are modeled after the letter V, and the thongs which adjust, or rather do not adjust, girths and stirrup-straps are knotted precisely under the knee—it is as necessary to take a test-ride on your saddle as on your horse before setting out on a journey of a few hundred miles; for the sum of the misery in actual pain and nervous irritation excited by straddling a rack strapped to a jerking-machine is beyond computation. Although for two or three days even a good horseman used to easy horse exercise reaches his camping ground, after a ten hours' ride, glad to lie down, and yet is uncomfortable even in a recumbent attitude, his limbs soon accustom themselves to their work, and he camps with a good appetite, and just enough of easiness to make rest welcome and his sleep sound. And you enjoy, under the open heaven, such sleep as nature never vouchsafes to the dwellers within plastered wall. On this point you and your *mosso* are sure to come to issue. If he can reach a *hacienda*, he delights to shut you up in some dreary abandoned room, with blank windowless walls and a single door. The immediate neighborhood of a village, with its biped and quadruped thieves, is not a camping ground to be preferred, and therefore you may be forced to take refuge within doors; but beware of a whitewashed room. Mexican cleanliness among the populace is confined to wearing spotless white cotton shirts and trousers, and whitewashing the walls and ceilings. How the animalcula that frequent the Mexican person resent the clean clothing is a matter for speculation; but very short experience teaches the traveler that whitewashing the walls simply drives all the flees on to the floor.

Unfortunately for his pleasure, the measure of the traveler's fatigue does not determine the length of the day's ride, but the presence of water, wood, and fodder. Hence it is not possible to cut up the journey into so many equal parts. But an average of forty-five miles a day can be got out of good animals without inflicting injury to the horse or his rider.

It is not many years ago since traveling was dangerous from robbers and murderers, and blood-curdling stories are told of the atrocities committed at certain favorite spots. But with the decline of State and federal political revolutions of late years, has declined the prevalence of crime, partly because the commission of one form of crime being repressed, the criminal classes, political and other, are deterred from indulging their propensities in other directions by desuetude; partly because there has really been exercised of late that function of government that consists in punishing wickedness and vice. It is refreshing to see the jail-gang, a good many dilapidated Yankees among them, sweeping the Chihuahua streets. As a result, robbery and murder are rare, remarkably rare, considering the opportunity which the scantiness of the population offers for their commission with impunity. Nevertheless, it is not well to go unarmed. A display of fire-arms undoubtedly excites reflection in the mind of the evil-disposed. But it is not conducive to prompt action in case of danger to so encumber one's self with weapons of offense and defense that one looks like a peripatetic armory. The most useful fire-arm to carry is a combined rifle and shot-gun. A good shot can keep a party in game almost everywhere. Partridges and wild turkeys are by no means scarce. Rabbits abound, and a small red deer every now and then faces you, apparently less alarmed at meeting you than you are astonished at seeing him.

J. D., JR.

THE LAW AS AFFECTING MINING AND METALLURGICAL INTERESTS.

THE CONDEMNATION OF NON-MINERAL LAND FOR MINING PURPOSES.

The decision of the Secretary of the Interior, confirming that of the Commissioner of the General Land-Office in the case of the Overman and Caledonia silver mining companies *vs.* John Maxwell *et al.*, applicants for patent for the Yankee mining claim, Carson City, Nevada, is of sufficient importance to warrant its publication entire. The Secretary says:

Said Yankee mining claim was duly located and recorded April 21st, 1876, as containing fifteen hundred (1500) by six hundred (600) feet, situated in Gold Hill Mining District, Storey County, Nevada. The application for patent was filed in the office of register and receiver, December 10th, 1878, and within the period of publication of notice, namely, February 6th, 1879, two adverse claims were filed by said Overman and Caledonia companies respectively. Said companies are owners of certain mining claims upon the Comstock lode; and for the purpose of working the same at great depths, found it necessary to sink a deep shaft at a point about four thousand feet to the east of their said claims, whereby they could reach the lode on its dip at the requisite depth. For this purpose, they desired to obtain possession of three certain tracts of land. Two of these tracts were in conflict with the said Yankee mining claim. In order to obtain possession of said tracts, the plaintiffs, on the 17th day of September, 1878, commenced proceedings under an act of the Legislature of said State, on behalf of said Overman Silver Mining Company *vs.* John Maxwell, Philip Corcoran, and divers other persons, but including all the persons who were afterward made defendants in the said suit, brought upon filing adverse claim. Said petition alleged the non-mineral character of the land; and the defendants, in their answer to the petition, set forth and asserted its mineral character. Upon that question, at the trial, a large amount of testimony was taken, and it was found and decided by the court that the land was non-mineral; and upon further finding the necessity for the use of the land, judgment was rendered in favor of the petitioner. Upon appeal by the defendant to the Supreme Court of said State, the judgment of the court below was affirmed.

In the suit brought upon filing said adverse claims, the complaint sets forth at length the proceedings in the condemnation suit, and insists that the determination in that suit in respect to the mineral character of the land is binding upon the defendants. In their answer, the defendants aver the mineral character of the land. When said adverse suit came on to be tried, the defendants offered to prove the mineral character of the land; but upon objection, the court held that the determination of that question in the condemnation proceedings was conclusive between the parties, and excluded the testimony. Thereupon the jury, upon instructions from the court, rendered a verdict for the plaintiff, and judgment was duly entered thereon. The judgment-roll in that case, and also in the condemnation suit, are filed as exhibits in this case. In your letter of March 23d, 1881, you review these proceedings, to show that the land in controversy was subject to exploration and purchase, and that you "must hold that the law has cast upon the executive department the duty of disposing of the public land, and, as a necessary incident, the authority of determining whether certain tracts are subject to sale under certain laws." You therefore directed the register and receiver to notify all parties in interest that a hearing would be had before them to determine the following points, namely: First. "Whether the land is valuable for its mineral deposits?" Secondly. "If so, whether the Yankee location is a legal one?"

The respective parties were duly notified, and appeared, and a hearing was had before the register and receiver. Upon such hearing, all the testimony taken in the condemnation trial was given in evidence under a stipulation to that effect between the parties, together with all the proceedings had at such trial and in the Supreme Court of the State on appeal, and also the proceedings in the trial upon the adverse claims; and in addition to such testimony and proceedings, further testimony was taken at said hearing. Such being the situation of the case as presented to me for my decision, I do not deem it necessary to discuss the questions presented by the record and briefs as to the legal effect of the condemnation proceedings, or of the ruling of the court excluding the defendants in the suit upon the adverse claims from giving evidence of the mineral character of the land in dispute. The parties have acquiesced in the order made by you, and the question of fact as to whether the Yankee mining claim contains a vein or lode bearing minerals is the only one necessary for me to determine. In considering this question, it is undoubtedly competent to take into consideration the decision of the district court. The present case, however, does not require me to decide whether or not that decision is conclusive or binding upon this department; and upon that question I express no opinion. A large part of the testimony upon both sides in the condemnation suit was directed to the question of mineral character. The testimony seems to have been carefully considered in the case, and the Supreme Court of the State, upon a review of the facts and the law, affirmed the decision of the district court. Upon the hearing ordered by you, the judge who presided at the trial of the condemnation suit was called as a witness, and testified that he had had a large experience in trying mining cases in that district; that he went upon the ground and into the shaft, and made a personal examination of the claim in respect to its mineral-bearing qualities, before rendering his decision in the case. Upon the hearing so ordered by you, the applicants gave little or no testimony on their part, but rested their case on the questions of fact upon the testimony adduced by them in the trial in the condemnation proceedings. The decisions of the district court and of the Supreme Court, of the register and receiver, and of your office all agree in the conclusion that said Yankee mining claim contains no valuable minerals or lode. I have also arrived at the same conclusion. In addition to the testimony given upon the trial of the condemnation suit, the protestants examined a number of witnesses upon the hearing ordered by you. Since the Overman Company entered upon the land in 1878, a shaft has been sunk to a great depth upon the ground in controversy, at an expense of some half-million of dollars, and no mineral-bearing rock has been disclosed in sinking such shaft. The testimony given at the hearing very strongly corroborates that given by the protestants upon the trial of the suit. Taking into consideration all the testimony in the case, and giving it due weight, it clearly establishes the conclusion before stated. Your decision dismissing the applications for patent is therefore affirmed.

Very respectfully, M. L. JOSLYN, Acting-Secretary.

NEW BATTERY SCREEN.

A new form of battery screen for quartz-mills has just been patented by Mr. Andrew S. Hallidie, the well-known wire manufacturer of San Francisco. Ordinary screens are made of a single sheet of punched metal, or piece of wire-cloth of the desired size of mesh. These screens are secured on a frame which is held in place in the grooves in the battery front by means of wedges. Whether of punched metal or wire-cloth, the screens are always of flat pieces. Mr. Hallidie, according to the *Mining and Scientific Press*, branches out with the new idea of constructing the screen with angles or corrugations, so as to give more screen surface to the given size of battery opening. In the construction of the improved screen, he employs woven wire, punched metal, or any other suitable screen material, and bends or corrugates the material into angular faces or flutings. Supporting rods or bars are fixed in the screen frame, so as to pass down in the angles of the corrugations and give any desired degree of stiffness. In order to retain these screens in position, they are fixed in frames which are shaped to fit the openings in the mortar in which the screens are to be placed. The top and bottom rails of these frames have corrugated slots or grooves formed in them, corresponding with the shape of the corrugations of the screen, so as to hold them firmly in place. The screen made in this way, instead of presenting a vertical flat surface to the splash of the water, presents a series of V-shaped faces, the screen surface being thus relatively increased, and the screen stiffened and strengthened. Mr. Hallidie is confident that this construction will make the screens last much longer, as they are not so apt to "bulge" and become broken as those of ordinary construction.

THE Lechner Manufacturing Company, Columbus, O., manufacturer of elevating and conveying machinery, has received an order from the Columbus & Hocking Coal and Iron Company for a chain elevator for elevating coal at its mines at Sand Run, O. It has also made a shipment of a steel roller chain to P. D. Pugh, Yazoo City, Miss., for propelling steamboats.

THE WORKS OF THE ALBANY & RENSSELAER IRON AND STEEL COMPANY.

Digitized by Google

THE WORKS OF THE ALBANY & RENSSELAER IRON AND STEEL COMPANY, TROY, N. Y.

The works of the Albany & Rensselaer Iron and Steel Company, which the members of the American Institute of Mining Engineers will visit during the course of the next week, is a group of establishments formerly owned by independent firms. The Albany Iron-Works grew up under the ownership of Corning & Winslow; the Bessemer Works, the oldest of the plants now at work in this country, were started by Winslow, Griswold & Holley in 1865. The Rensselaer Works, a mile farther up the Hudson River, after upward of thirty-seven years' growth, were joined to the Bessemer Works. These different establishments are now consolidated into one large company, the Albany & Rensselaer Iron and Steel Company, of which Robert W. Hunt, the President of the American Institute of Mining Engineers, is general superintendent. The visitors will, in some departments, in some of the oldest works, find portions of the plant that remind them of the long period since which they have been at work; but they will be more struck in every direction by the evidences of a prudent desire to substitute the most modern machinery, plants, and appliances for those of an older type. These changes have been and are now gradually made, and it will not probably be long before the oldest features of the plant disappear as they become unserviceable. The disadvantages incident to the distance between some of the establishments, though closely allied in their work, as, for instance, the Bessemer mill and the rail and merchant steel mill, have been as much as possible overcome by a system of narrow-gauge railroad which connects these works, situated a mile apart. Being located on the banks of the Hudson, they have special facilities for receiving raw materials, including foreign Bessemer pig, and for shipping; cheap water transportation, too, to some extent modifying the disadvantage of being located at a great distance from the coal regions. The railroad facilities are exceptionally good, and give access especially to the adjacent New England markets.

The Bessemer Plant.—Before work was begun at this, the first Bessemer plant doing more than experimental work, a number of different American irons were experimented with at Sheffield in 1864, and a Lake Champlain iron, the Crown Point, was found especially good. A 2½-ton single vessel plant was started in February, 1865, and run until 1871, when it was changed into an ingot mold foundry. The present works were started in 1867 with two 5-ton vessels. They were partially destroyed by fire in 1868 and were rebuilt in 1869, work beginning in 1870. More recently larger cupolas and 7-ton vessels were put in. Since A. L. Holley's description of the works in *Engineering*, to which we are indebted for many details and drawings, kindly corrected to date by Mr. H. W. Shaw, four spiegel cupolas and a ferro-manganese pre-heating furnace have been put up. The Bessemer building, a plan of which is shown in Fig. 1, is 148 feet by 98 feet, with a cupola-house 80 feet by 39 feet. The vessels are set high side by side and with three ingot cranes over a shallow pit. The 7-ton vessels have 6 feet internal diameter, and 15 tuyeres with 12⅝-inch holes. They receive an average charge of 18,000 pounds. The vessel bottoms, which on an average stand 14 blows, are interchangeable, and are removable by means of lifts and of cars which carry them laterally, for repairs, under the two-side ingot cranes. They are baked in adjacent ovens. The blowing-engine and pump-room are conveniently placed on the right of the vessels, and the blooming-mill (formerly a hammer-shop for cogging ingots) comes next. As the departments grew gradually and experimentally, and were not expected to exceed 60 tons of product per day, the buildings are not of the size and arrangement that would now be made; but by means of convenient transporting apparatus, as high as 600 tons of hot ingots per twenty-four hours are delivered by power into the blooming-furnaces, and are rolled, cut up, and chipped, under a 7-ton hammer, and loaded hot on the rail-mill cars with reasonable facility.

The Bessemer blowing-engine has a pair of 54-inch diameter by 5-foot air-cylinders. It had a pair of 42-inch steam-cylinders, but a 72-inch low-pressure steam-cylinder has been substituted for one of them, and, with an improved condenser, the engine now gives a good economy of fuel. The valves of the low-pressure cylinder and a similar change of the high-pressure valves is contemplated. It indicates 500 horse-power at from 24 to 26 revolutions, with 70 pounds boiler pressure, while blowing 7 tons of metal through 180 ⅝-inch tuyere-holes at 20 pounds pressure. The four cupolas, which running together melt the iron for 600 tons of steel per twenty-four hours, are driven by two No. 7½ Baker rotary (revolving piston) blowers. They deliver air at 14 ounces pressure, and can blow 1½ pounds. A third is being put in. Blast for the spiegel cupolas is provided by a Sturtevant fan. The iron cupolas, of the ordinary deep bottom type, are 21 feet high and have a 5½-foot minimum internal diameter. They have eight 5 by 8-inch tuyeres, and melt 12 pounds of iron per pound of fuel. The latter consists of 65 per cent of anthracite and 35 per cent of coke, which keeps the charge loose and allows the blast to penetrate it freely. Four spiegel cupolas furnish the required quantity of spiegel, which is run into a ladle so arranged that, in tipping over, the ladle is slightly advanced, so as to pour out the charge quickly and completely. The materials for the two sets of cupolas are brought up to the charging-floors by two Otis hoists. There are two large Worthington compound duplex pressure pumps. The larger one is illustrated by Figs. 4 and 5, Plate I. It has a pair of 21-inch and a pair of 36-inch steam-cylinders, and four 9½-inch plungers, with 3-foot stroke. The smaller has 33⅜-inch and 19½-inch steam-cylinders, 9-inch plungers, and 24tinch stroke.

The average production of the Bessemer plant is 12,000 tons of ingots per month. It has a record of 604 tons in one day, 3150 tons in one week, and 13,693 tons in one month.

The three-high blooming train was the first started in America, running for the first time in January, 1871. It is driven by a direct condensing-engine, with 36-inch cylinder and 4-foot stroke, and, running at 40 revolutions per minute, rolls the product of the converting-works from 15-inch ingots to 7-inch four-rail blooms by the labor of four men and boys. There are in the blooming-mill five reheating furnaces, all of them being charged and discharged by power. They are heated with bituminous coal. One of them, the last built, is to be provided with a boiler, the setting being a new type, the outgrowth of the experience at the works. The last furnace has also an arrangement for cooling the doors and frames with water, which the visiting engineers will do well to examine more closely. The water is first carried around the door-frame and then into the door, which is open at the top. The other furnaces in the mill are also to be provided with these water-doors and frames, which experience has shown work satisfactorily.

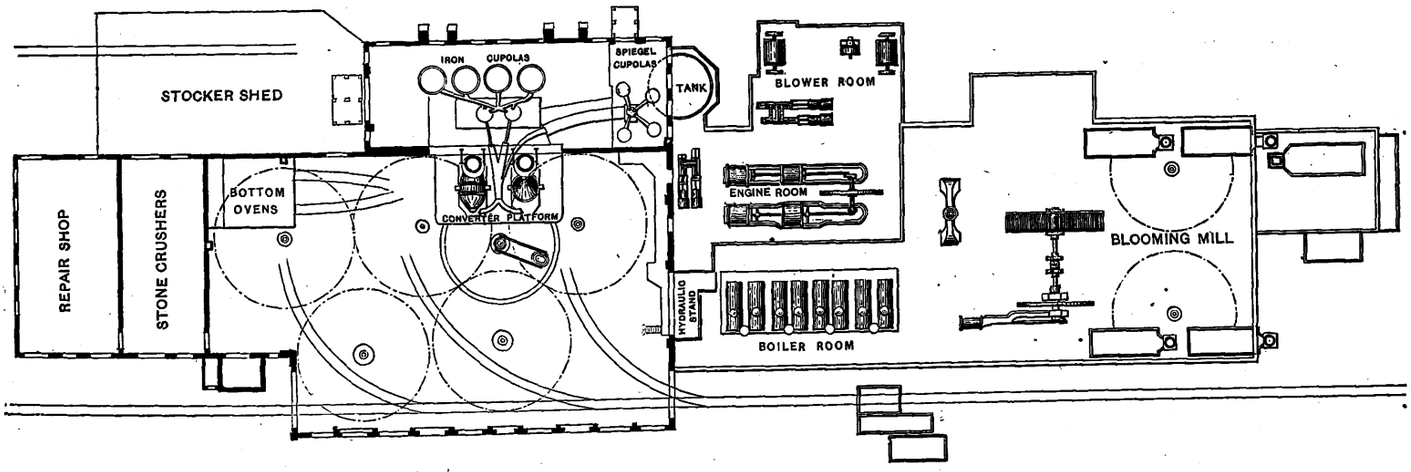

Fig. 1.—The Bessemer Mill.

The blooms rolled on the blooming train are cut into lengths by a hammer. Those not immediately carried by train to the rail and merchant mill are stored, and are subsequently handled by traveling cranes.

The Rail-Mill, a plan of which is shown in Fig. 4, is a brick building 375 by 98 feet, with the wings as shown. There are thirteen heating-furnaces *B D*, fired with bituminous coal, all but one having a horizontal over-head boiler with return flues. Ten are shown in our engraving. The train *A* is 21 inch, three-high, with three stands of rail rolls next the engine and two stands of merchant rolls arranged to deliver to the rail-sawing and finishing apparatus. The whole mill can thus be utilized as a merchant mill for medium and heavy work when this pays better than rails, or both rails and merchant steel can be produced in different turns when there is not demand enough for either product to alone fill the mill. The train has a conveyer, designed by Max Supper, for carrying off sideways automatically the scale accumulating below the rolls. When running on rails, the average output of the train is 1800 tons. It has, however, a record of 2350 tons per week. The rail-train engine is vertical condensing, with 3-foot stroke, a 44-inch cylinder, and Corliss valve-gear. With a boiler pressure of 70 pounds, it runs at a speed of 80 revolutions. The mill is provided with a Gustin hot curving apparatus and a double hot bed and finishing machinery. In one of the wings, are a number of punches and shears for cutting steel into the many shapes used for agricultural machinery.

Particular attention should be given to the press designed by S. Baldwin, of New York, for utilizing rail crop ends. The object is to press the foot of the rail into such a shape, similar to that of the head of the rail, that in afterward rolling down the crop ends sideways, it will make a plate. The difficulty is to remove the tendency of the thin foot to bend over instead of gathering together in a body having approximately a round form. Unless that form is attained, seams are created by doubling up of part of the material, and these can not be got rid of in any subsequent rolling. For some sections, the press appears to do its work admirably, so that the plate rolled from it can be used for nail plate, etc.

The Merchant Steel Mill.—The main brick building of this mill is 338 by 187 feet. This mill has an 18-inch three-high merchant train *A*, for rolling a general run of 18-inch train sizes of billets and merchant steel. It is also used for iron fish-plates. The sheet-train *B* is 18-inch, three-

Digitized by Google

high, and produces ten tons out of one furnace and an annealing furnace. Both trains are driven by a 60-inch by 10-foot beam-engine, which formerly belonged to the steamboat Swallow, which was burned thirty miles below, forty years ago. It has been recently overhauled by the Delamater Iron-Works, and is likely to see many more years of service.

A particularly interesting feature of the mill is two fast trains driven by Porter-Allen engines, which are specially adapted to work of this kind, as their use avoids the gearing. The fast 18-inch three-high train *C*, making 125 revolutions, produces per turn 50 tons of 1¼-inch 20-foot wire-rod billets from 7-inch blooms. The 9-inch three-high train *D*, also driven by a Porter-Allen engine, has been working until now only for one furnace. A second furnace, now building, will bring it up to full capacity. The mill has two Baldwin hot straighteners, improved by the engineers of the works.

The Albany Iron-Works.—These works are situated some distance from the Hudson River, at the back of the Bessemer works. The building is brick, 329 by 156 feet, with wings, and a roof with cast-iron trusses, cast in sections, one of the few probably of this design still standing. The mill contains a modern 18-inch merchant train, three-high, of the Fritz type. The train has three stands of rolls, and is driven directly at from 80 to 100 revolutions by a handsome Corliss horizontal engine, with 24-inch cylinder and 4-foot stroke, and a Bulkley condenser. This train is used for making a general run of merchant sizes, finger-bars, fish-plates, angle iron, etc. For straightening the latter, there is a machine designed by Louth, which, however, to judge from its appearance is little used. The Belgian train *B* is driven by a Porter-Allen engine, being bolted to it two to one. The same engine, having a 22-inch cylinder and 3-foot stroke, drives a stand of 12-inch roughing rolls. The engine has seen some very hard service, and yet has stood up very well under the work, running for days at a speed of 200 revolutions, and occasionally obtaining a piston speed of over 1300 feet. Note may be made in passing of a curious accident which happened to it some time since. The engine had been carefully overhauled one day, and yet within twenty-four hours broke down. An examination proved that one of the springs of the piston had worked its way through three quarter inches of metal. The Belgian train is used for rolling wire rods and small sizes of merchant iron and special shapes, such as hexagons, octagons, half-rounds, etc. The train has rolled wire at the rate of from twenty to twenty-five tons per turn, the engine running at a speed of 200 revolutions and the finishing-rolls 400 revolutions. Behind the train stands a wire reel, designed by one of the engineers of the works, which deserves careful examination. It is simple, compact, and easily handled, and has, we understand, stood the test of very rapid work admirably. These two trains are supplied by four Swindell regenerative gas heating furnaces. The mill contains besides a Cuyahoga helve-hammer for axles, an 18-inch puddle train *D*, geared to a 44-inch by 6-foot engine, a Winslow squeezer, and a 3-ton hammer. A fly-wheel has recently been placed on the train-shaft, and by having the engine run faster, a large gear-wheel and shaft could be thrown out.

The puddling-furnaces in the mill have been considerably changed. They are double furnaces provided with a small hearth for preheating the pig. The result of this and other improvements has been, that 2200 pounds of Blossburg coal and from 750 to 800 pounds of Lake Champlain ore suffice to the ton of 2240 pounds of puddle bar. They enable two puddlers and two helpers to produce 6000 pounds of bar in five heats of 1200 pounds each. Some of the furnaces are furnished with boilers, the setting of which is the design of Captain J. H. Maes. The setting is gradually finding its way into all of the puddling and heating-furnaces in the mills.

The Star Forge.—This mill, shown in Fig. 7, is an irregular building containing a number of puddling-furnaces, some of them of old design, and a scrap furnace. It has a 16-inch puddling train *A*, and a 14-inch merchant train *D*, recently moved and equipped with a modern hot-bed. These trains are driven by a 30-inch by 4-foot condensing Corliss engine.

The Horseshoe Building is 212 feet by 90 feet, with wings. It contains two modern trains for small sizes, one of them driven by an old overshot water-wheel. The nail and spike factory has a large number of machines, its principal point of interest being that cut steel nails are manufactured in it.

The maximum production of the different establishments of the Albany & Rensselaer Iron and Steel Company is reported to us as follows, in gross tons per week:

	Tons.
Ingots	3,000
Rails	1,800
Merchant steel	900
Merchant iron	1,000
Pig-iron, Fort Edward furnace	210
Pig-iron, Port Hudson furnace	225

The works employ about 2500 men, to whom wages amounting to approximately $28,000 per week are paid.

THE BASIC PROCESS IN EUROPE.—From the *Bulletin du Comité des Forges de France*, we take the following statistics of the production of steel by the basic process, during the first six months of the present year:

	Number of converters.	Product. Tons.
England	1	57,900
France	2	5,960
Belgium	1	12,786
Germany	9	152,479
Austria	3	37,476
Russia	1	12,786
Total	17	279,387

In 1882, 6½ million tons of ingots were produced in the whole manufacturing world. As will be seen from the above figures, this process has met with the greatest favor in Austria and Germany; in the former country, it produces 28 per cent of the steel made, and in the latter 25 per cent, while it is only adopted to the extent of 5 per cent in England. In this country, it is in use only at one mill, that of the Pennsylvania Steel Company, near Harrisburg.

THE DUTY ON WIRE RODS.

The Secretary of the Treasury Department has issued the following circular, dated September 21st, transmitted to us by our Washington correspondent:

Several questions have been presented to this department as to duties on iron and steel under Schedule C of the Tariff of March 3d, 1883, and for the information and guidance of all concerned, the instructions below are promulgated. The fifth paragraph of Schedule C (T. I., new, 148) is as follows:

"Bar-iron, rolled or hammered, comprising flats not less than one inch wide, nor less than three eighths of one inch thick, eight tenths of one cent per pound; comprising round iron not less than three fourths of one inch in diameter, and square iron not less than three fourths of one inch square, one cent per pound; comprising flats less than one inch wide, or less than three eighths of one inch thick; round iron less than three fourths of one inch and not less than seven sixteenths of one inch in diameter, and square iron less than three fourths of one inch square, one and one tenth of one cent per pound: *Provided*, That all iron in slabs, blooms, loops, or other forms less finished than iron in bars, and more advanced than pig-iron, except castings, shall be rated as iron in bars, and pay a duty accordingly; and none of the above iron shall pay a less rate of duty than thirty-five per centum *ad valorem*: *Provided further*, That all iron bars, blooms, billets, or sizes or shapes of any kind, in the manufacture of which charcoal is used as fuel, shall be subject to a duty of twenty-two dollars per ton."

Provision is made in the same schedule for sizes and shapes of iron other than those named in the paragraph above cited; and the first question presented is, whether the last *proviso* cited above applies to any iron other than that named in the paragraph which precedes it. On this point, the department decides that the provision for charcoal iron applies only to the iron otherwise dutiable under the paragraph in which it is contained.

The same schedule contains the following provisions:

(T. I., NEW, 150.)

"150. Round iron, in coils or rods, less than seven sixteenths of one inch in diameter, and bars or shapes of rolled iron not specially enumerated or provided for in this act, one and two tenths of one cent per pound."

(T. I., NEW, 180.)

"180. Iron or steel rivet, screw, nail, and fence, wire rods, round, in coils and loops, not lighter than number five wire gauge, valued at three and one half cents or less per pound, six tenths of one cent per pound."

The department decides that paragraph 180 contains the provision which must govern the rate of duty on the merchandise specially described therein.

This leaves round iron in coils and loops, not lighter than No. 5 wire gauge, valued at 3½ cents or less per pound, not rivet, screw, nail, and fence wire rods; round iron in coils or rods, lighter than No. 5 wire gauge, or which is valued at more than 3½ cents per pound, and bar iron, round, less than $\frac{7}{16}$ of an inch in diameter, which is not enumerated in paragraph 148, liable to duty under paragraph 150.

It is borne in mind that section 2499 of the new tariff provides that, if two or more rates of duty shall be applicable to any imported article, it shall be classified for duty under the highest of such rates, but it is held that this provision does not affect the rate of duty on articles comprised in paragraph 180, which are specially provided for.

DIAMOND MINING IN THE PROVINCE OF MINAS-GERAES, BRAZIL.

The discovery of the first deposits of gold in the province of Minas-Geraes, the most productive in Brazil, led to the search for diamonds as early as the close of the seventeenth century, the first being found at Serro. The fever spread, and, moving northward into virgin country, founded the village of Tijuco, the Diamantina of to-day and the center of diamond mining in Brazil now. M. A. de Bovet, professor at the School of Mines of Ouro-Preto, Brazil, has recently, in the *Annales des Mines*, Paris, printed an exhaustive and highly interesting account of a visit to that section, and from his paper on the history and present status of the industry we have gathered the following notes.

At Diamantina, as elsewhere, the river-beds were first worked for gold, and tradition says that, while the miners had noticed the existence of bright stones in their pans, and had collected them as curiosities, it was only when a passing traveler revealed to them their value that they began to gather them. All that is definitely known is, that in 1729 the Portuguese government was informed of the existence of diamonds in the vicinity of Tijuco. The government at Lisbon promptly ordered the authorities of the province to issue ordinances designed to secure to the government the largest possible share of this new source of wealth. Compared with others which followed, the first laws were liberal. They simply withdrew the titles to all claims for gold washing already allowed, permitted only mining for diamonds, distributed the ground anew, allowing no one person to hold more than 86 feet square for every hand employed, and levying a sum of 28 francs for each person at work. Contradictory orders followed one another in quick succession, and the impost per hand was rapidly run up to 224 francs per man. In 1734, the government ordered the entire cessation of work until it had devised such methods as promised to yield it the largest returns. After five years of suspense, the government finally decided to farm out the mining of diamonds. An administration was created at Diamantina, at the head of which was a functionary, bearing the title of "intendant of diamonds," whose duties were to carry out the laws and hold the contractors working the mines to their agreement. The contractors, who were assigned a certain territory, had to employ a given number of slaves, usually six hundred, and could not under any circumstances employ more. Between 1740 and 1761 six such contracts were let, and the contractors had to pay for each man employed, whether he was working or not, a sum which was gradually raised from 1288 to to 1844 francs. The contractor had to send his diamonds to Lisbon, where they could alone be sold. While such were his obligations, he had,

Digitized by Google

on the other hand, the exclusive right to mine. The intendant had to guard his right and carry out the laws enacted for his protection, among which the following may be quoted to show how severe the restrictions were. No person was allowed to buy, sell, or export diamonds under heavy penalties. Accusations from informers, even if secretly made, were received by the authorities, and where they led to conviction, one half of the confiscated articles belonged to the informer, who, besides, if he was a slave, was given his liberty. No person was allowed to enter the diamond district without special permission of the intendant. If a merchant, he had to state the character and value of his goods, and on leaving the district prove an equal quantity of value. No one was allowed to possess any tools except those required for his work. With all these safeguards, there was a large class of men, called garimpeiros, who did mining on their own account, their principal difficulty being to get tools. It is stated that slaves who had escaped made them from the chains around their necks. Both the government and the contractors had bodies of men in their employ whose sole occupation was to hunt down this class of men.

Some of the contractors did an enormous business, in certain cases very lucrative. Two of them had all or a part of their possessions confiscated under trumped-up charges.

After the sixth contract, the Portuguese government, which had adopted the system mainly to ascertain the results that regular working of the mines would lead to, decided to work them on its own account, and in 1772 the administration at Diamantina was charged with it.

The intendant became all-powerful. He was the executive who carried out the laws, and was the only judge, having no tribunal to aid him. There was no appeal from his decisions, and, as the regulations put it, he was to judge as rapidly and with as little formality as possible. Some modifications were made of previous laws. Two of them are curious enough to be mentioned. The first absolutely prohibited the entrance into the territory of any one who had ever studied law. The second referred to informers. Any informer could carry his statement, written, but not signed, to the intendant, who dated and indorsed it, and gave it back to the one who had submitted it. From this moment, this slip of paper could be transferred to any body, could be sold and bought. It was a bill to bearer. When the process against the person accused had been decided, and the confiscation had been made, the bearer, whoever he might be, had the right to claim his share of the amounts confiscated. If the bearer was a slave, he obtained his freedom besides. This new system, begun in 1772, was carried out more or less rigorously according to the individuality of the ruling intendant, until the year 1845, when it was officially abolished, although after 1822 it languished, from the absence of funds.

The administration bought a certain number of slaves from the last contractor and hired others throughout the country. When it paid well for them, their owners hired them gladly; but when the mines were not doing well and they could not pay much, the government generally succeeded in getting the slaves by threatening the owners. Thus it generally had a good force, and at times employed more than 4000 slaves in the mines.

Little is known as to the quantities of diamonds obtained during the period when the contractors had charge of the mines. For the time when the government worked them, accurate figures are available. From 1772 to 1845, the produce was 269,870 grams of diamonds, there being 80 stones exceeding 3·5 grams in weight. In twenty-three years, from 1772 to 1795, 174,842 grams of diamonds were mined at a total expense of 38,706,090 francs, besides 3,169,460 francs worth of gold. The average cost declined from 208 francs per gram during that period to 195 francs between 1796 and 1801, and 162 francs between 1801 and 1806.

THE DIAMOND DEPOSITS.

Diamonds are found in Brazil in the provinces of Minas-Geraes, Bahia, Parana, Matto-Grosso, and Goyaz. In Minas, they are mined at Diamantina, Grao-Mogol, Bagagem, Conceicao Cocaes, and other points, the first named, however, being the most important. Diamonds are found in a rounded gravel having peculiar characteristics, which is called by the miners "*cascalho.*" It is a mass of small pebbles, chiefly quartz, mixed with very little clay. If examined with care, it will be found to contain a large number of minerals, many of which are present in the cascalho from all the districts. At Diamantina, Gorceix has discovered rutile, anastase, arkansite, tourmaline, titanite, fibrolite, klaprothine, psilomelane, disthene, pyrite, magnetite, garnet, talc, mica, staurodite, sphene, euclase, and gold.

The cascalo, itself occurs in the form of deposits in the river-beds, on the river-banks, sometimes at a considerable altitude, and in high plateaus. The existence of the diamond gravel in the river-beds explains itself. It is generally rich, and contains a greater number of large diamonds near the sources, and finer diamonds at a greater distance from them. The gravel is pretty irregularly distributed in the river-beds, and generally reaches its greatest richness in what is called a *caldeirao*, or kettle. The caldeirao is an almost spherical excavation, becoming cylindrical when it is deep, cut into the bed-rock. It has smooth sidewalls, as though it had been drilled out. Such caldeiraos are found when the character of the ground has tended to produce eddies, and it will be understood how the stones carried about by this movement, and for long periods turning on the bottom, should have ended in making these excavations. They are even found in rivers which do not carry diamonds. The diamonds, of course, not only cut the bed-rock, but also the pebbles moving with them, until they were reduced to such a state of fineness that they were carried off. By this action, the diamonds accumulated and the cascalho was enriched. The miners well know this, and consider those points of the river which tend to produce eddies particularly favorable. Nowadays, this indication has lost much of its significance, because the rivers have been worked over so often that there is the greatest uncertainty as to whether the ground is virgin or not. The diamond gravel is covered with a layer of boulders of considerable size, which must be generally blasted to be removed. Above it is generally sand of recent origin which is absolutely barren. The thickness of the latter varies a good deal. Sometimes it is only from 5 to 15 feet; sometimes, at points where the river-bed has been much deepened, or where a picao or pit has been formed, in the shape of an enormous caldeirao, the bed of barren sand reaches a thickness of from 75 to 100 feet. These, of course, are rich spots, but they are very difficult to work.

The bank deposits, at least those not high above the river-bed, may have been formed in the same manner as the river deposits when the streams carried a much greater body of water. They are also covered with a layer of barren material. As for the plateau deposits, their origin is more doubtful. They consist of a coarse cascalho gravel scattered over the surface without being covered, so that the miners say, that diamonds may be found at the grass-roots.

THE Murphy Champion Ventilator has now been in successful operation for ten years, and its merits as a ventilator for mines and tunnels are well established. Messrs. Fraser & Chalmers, sole manufacturers of this ventilator, have issued an illustrated catalogue fully descriptive of the machine. The ventilators are made from 3 feet to 10 feet diameter. The sizes generally used are as below: 4-foot fans, all complete, including all wood-work, without engine or main belt, weight 3300 pounds, costing $450; 6-foot fans, including all wood-work, weighing 6000 pounds, costing $650; and 8-foot fans, including all wood-work, weighing 13,000 pounds, costing $1000. The cost of belt for driving ventilator depends upon its length, the location of engine to pulley on the ventilator determining this. Generally, the steam for the engine driving the ventilator is taken from the hoisting-works boilers at the coal shaft. If power is wanted for driving ventilators, the builders advise: Engine 5 by 6 for 4-foot ventilator, weight 1200 pounds, cost $225. Engine 6 by 10 for 6-foot ventilator, weight 1800 pounds, cost $300. Engine 8 by 12 for 8-foot ventilator, weight 2800 pounds, cost $450.

FURNACE, MILL, AND FACTORY.

Messrs. Fraser & Chalmers, of Chicago, have just concluded a contract for a 40-ton copper smelting-furnace all complete with blast-pipes, water-pipes, Baker blower, crusher, engines, boiler, etc., for the Concordia Mining and Smelting Company, Mexico.

The Solid Steel Casting Company, Alliance, Ohio, an outgrowth of the Morgan & Williams heavy engineering business, is now in full operation. The works are established for the purpose of supplying heavy steel parts of mechanical appliances and machinery in place of iron, and have a process for casting steel which has been thoroughly tested.

The plate and sheet-mill of the Laclede Rolling-Mills, St. Louis, has been started up, and other departments of the works will probably be put in operation later on.

The Johnstown *Tribune* reports that, in accordance with notices posted throughout the buildings, the Gautier wire-mill closed down on Saturday evening, September 22d, and will remain idle for one week, or until repairs that are necessary have been made. The temporary stopping of the works will also afford an opportunity to reduce stocks, which are large, and somewhat greater than the actual demand.

In the suit in equity brought by the Mount Hickory Iron Company, Limited, Sharpsville, Pa., against James B. Pierce, manager of the Mount Hickory Furnaces, with the object of ousting him from the position, Judge McDermitt has filed his opinion refusing the injunction asked.

The Calumet Iron and Steel Company, of Chicago, has just finished experiments which have resulted in the perfection and erection of a plant for the manufacture of steel nails.

Messrs. Fraser & Chalmers, of Chicago, are now erecting at the works of the Eckstein White Lead Company, Cincinnati, O., a Corliss engine 26 by 48, with a large amount of shafting, pulleys, etc.; for the Bismarck Elevator Company, Bismarck, Dakota, a 12 by 26 Corliss engine, two boilers 44 by 14 feet, and other machinery; for the Miltimore Car-Wheel Works, just organized, about to be built at Garfield, one of the suburbs of Chicago, a Corliss engine 22 by 48, with two tubular steam-boilers 60 by 16 feet; and they have recently completed at the brewery of John F. Betz & Sons, Philadelphia, Pa., two Corliss engines 18 by 42, with air-pumps and machinery of the Boyle Ice-Machine Company's design. They are also building for the Boyle Ice-Machine Company two 15 by 30 Corliss engines, for Ohio, with ice-machines complete, and two of the same size for Texas.

The Linden Steel Company, Limited, Pittsburg, has completed the erection of a 20-inch plate-mill, and has every thing ready for sheet and plate of tank and boiler qualities. This makes two plate and sheet-mills (one of 18 inches and the other of 20 inches diameter), one bar-mill (18-inch), one rod-mill of 10 inches diameter, one universal mill, and three hammers; showing that the company has increased its capacity very greatly.

An axle made of the "Refined Bessemer" produced by the Pittsburg Steel Casting Company, stood what is considered an extraordinary test: Three blows at 10 feet, two blows at 15 feet, two blows at 20 feet, and five blows at 27 feet, with a drop weighing 1640 pounds, reversing axle each blow. The operation was continued until those testing decided that, if they continued hammering all day it would not break. A round of soft steel was hammered while cold, with a steam-hammer, water being poured on the faces of the anvil to keep them from heating. This was continued until the round was flattened out, not the slightest crack appearing. This same steel pulled 71,400 pounds, showed a reduction of 80·6 per cent at point of fracture, elongation in 8 inches of 28·7, limit of elasticity 49,400 pounds.

The Gates Iron-Works, Chicago, have just shipped one of their No. 5 crushers with elevator and screens to the Philadelphia & Reading Railroad, to be erected at Hopewell, New Jersey. They have also consigned a number of smaller crushers to towns in Illinois, Indiana, and Pennsylvania for breaking rock for street-paving, and also a No. 3 crusher to Blairsville, Pa., for use on the Pennsylvania Railroad.

The Harrisburg *Patriot* of a recent date says: The largest run ever made at the Pennsylvania Steel Company's works, Harrisburg, was that of Thursday, and it is pretty safe to say that it has never been equaled in any part of the world. In twenty-four hours, three turns were put to work, each being employed for eight hours. The first turn, known as "C," started on Wednesday at two o'clock in the afternoon, and quit at ten o'clock at night. In that time, 53 heats were made and 954 rails turned out. The "A" turn relieved the "C" men, and continued until six o'clock the next morning. Fifty-four heats were made and 972 rails. The last turn, "B," eclipsed each of the others by making 57 heats and 1026 rails. During the entire twenty-four hours, 164 heats were made and 2952 rails turned out, being an average of 2⅛ rails per minute.

E. W. Blatchford & Co., of Chicago, are building a new addition to their works, 80 by 100 feet in size and three stories high. They will also add a large amount of new machinery, embracing a complete mill for sheet and bar lead, a shot-tower, etc., and otherwise greatly increase their capacity.

Contracts have recently been awarded to the Keystone Iron-Works Company, of Kansas City, for the construction of four slide-valve engines of 50 horse-power each, and boilers for the same, and for one automatic engine. This company has just completed a double hoisting-engine, of 70 horse-power, for the Rich Hill Coal Mining Company, and a 25 horse-power engine and boiler for the

Digitized by Google

Huggins Cracker and Candy Company, of Kansas City. It has also recently built an engine and boiler for John Wuerth, Holton, Kansas, and one for W. C. Johnson & Co., Solomon, Kansas. This company is constantly adding new machinery to its plant. Among the specialties made by the company may be mentioned a patent pump, driven by two cylinders of 175 horse-power, for the smelting-works at Argentine, Kansas. By the use of this pump, the metal which heretofore has been lost through the flume is passed through the pump and saved. In the milling department, the company has just completed a 7-reel bolting-chest for a flouring-mill at Dodge City, Kansas.

The Hotel Oxford, on Huntington avenue, Boston, just completed, is furnished with four of the Whittier Machine Company's steam-elevators—two for high-speed passenger service, two for freight.

GENERAL MINING NEWS.

ARIZONA.

COCHISE COUNTY.

COPPER QUEEN.—Work continues as usual.

HENDRICKS.—The mine is leased to the Tombstone Mining and Milling Company, and produces ten tons of high-grade lead ore daily, which is shipped to Charleston.

TOMBSTONE DISTRICT.

The *Epitaph*, in its review of operations at the various mines, states that a satisfactory condition of affairs is shown throughout the district. The quantity of ore daily extracted is fully up to the average, while the bullion product at the mills shows no diminution in the richness of the ore. The steady progress made on the Contention pumps is gratifying, and the announcement that the anxiously awaited work of draining the lower levels will be commenced on December 1st will be hailed with rejoicing throughout the camp. Fears have been entertained by some that the capacity of the new pumping machinery would not be sufficiently great to handle the volume of water in the lower levels of the hill properties. It is stated, however, by competent authorities in Tombstone that such fears are groundless, and that the Contention pumps, when in place and worked in conjunction with those of the Grand Central, would be enabled to successfully overcome a much larger body of water than that with which they will have to contend.

GIRARD.—Work has been resumed.

PEABODY.—A strike of a new body of ore in this mine, which is located at Johnston, is reported. The thirty-ton copper furnace is running steadily, and there is some talk of the company erecting another large one of fifty tons.

SAN DIEGO.—The furnace is to be started up shortly at this mine, which has been idle for some months.

TOMBSTONE MINING AND MILLING COMPANY.—At the Luck Sure, the ore-body is increasing, both in quality and quantity, some of the ores carrying as high as forty per cent in lead, making the same a very desirable smelting ore. The shipping of 200 tons of ore to the company's furnace at Charleston has just been commenced.

WAY UP.—Since the last court decision, this mine has been under a lease, and quite a quantity of high grade ore has been extracted, the same milling from 97 to 800 ounces of silver to the ton.

MARICOPA COUNTY.

TIP TOP.—It is learned from the Phœnix *Gazette* that this mine, after having produced about $2,000,000, will shortly be closed down for good. The company's books show a debt of $95,000 over and above the production of the mine. By the sale of supplies, the superintendent realized sufficient to pay off all the debts at the mill and mine. He is now running the mill, working over a few tons of tailings. When this is done, the mill will be closed down and the last man discharged.

MOHAVE COUNTY.

THE LOS BASINS AND GOLD BASINS.—Writing from Williams, under date of September 3d, Mr. J. C. Bramwell reports to us as follows: While the mining fever is assuming such large proportions in our neighbor, New Mexico, it would be doing ourselves a great injustice not to speak of the precious metal which, though yet undeveloped in many sections of this territory, still bids fair to surpass even our own sister territory, and prove of incalculable value to those who have ventured to penetrate a section of country up to within a recent period in the hands of savages. This obstacle has now been removed by the advent of the railroad, which has reached the Colorado River. Here is the section of country called Los and Gold Basins, situated in Mohave County, Arizona. These two mining camps are as yet in their infancy; but according to the reports of one of the most reliable and best informed of mineral prospectors in this section, Mr. J. S. Coon, their resources can not be equaled for the amount of ore in sight. A thorough and searching examination having been made by him of these camps and surroundings, he is competent to speak on their merits. The following statement best describes the condition of the country: The camps above mentioned are 45 miles north of Hackberry, which is a stirring camp on the line of the Alantic & Pacific Railroad, containing a ten-stamp mill running night and day on free-milling silver ore. The road leading from here to the Los and Gold Basin camps is so smooth that a basket-phaeton could be driven from Hackberry to within one mile of the mines, without the slightest injury. The Colorado River runs on the north boundary of this camp, and will furnish water-power sufficient to turn all the machinery needed, and shafting up and damming can be done with comparative ease and safety. The road from the mines to the river leads down-hill; and ore has a natural drift in that direction, which makes the hauling of it merely nominal, and places the mill and mines in close proximity. There is a natural foundation for a dam and mill, there being a small mountain of granite in the center of the river at the head of the rapids, which would furnish a sure hold for the dam. The cost of water-power, compared with steam, makes the operation of milling the ores comparatively cheap. The formation of this country is granite, and the leads true fissures. They can be traced from one claim comrising 1500 feet to three and even five miles, and will assay from $25 to $300 per ton at the surface. The ore is mostly free milling. Some is base with copper; some contains from 0·9 to 22·8 per cent copper. On the east side of Los Basins camps, there are several good ledges of galena, with no development whatever. Little is yet known of these camps, as they have been examined by but one expert, and then only an imperfect examination was made. It revealed sufficient to convince him, from the large quantities of good ore above ground, of the great value of its mineral properties. It was here, where the small boulder of quartz was found containing $700; also the piece of float that assayed $96,000 to the ton; and the lead is yet undiscovered. On the Ida mine, there is a shaft 25 feet deep, showing a vein 7 feet in width. There is no other mine in Los Basins that has more than 12 feet of work done, and all ore taken out thus far is good milling ore. The camp is well supplied with water; no prospect being over six miles from the river. There are four springs in easy reach—Burro Springs, four miles distant; Grape Vine Springs, six miles; Grass Springs, seven miles; and Patterson Wells, six miles. This, for Arizona, is a decided advantage over other camps, which should not be overlooked. Work can be done the year around; but the winter season is the most pleasant. Snow seldom falls, and only in small quantities. The supply of charcoal is abundant; the timber being only fifteen miles from the river. If smelting be considered, coke can be had in sufficient quantity from Hackberry.

PIMA COUNTY.

TUCSON SMELTING AND MILLING COMPANY.—The county's appropriation of $15,000 in bonds to the person who erects the first smelter has attracted Aaron Mason to the scheme, and the above company has been organized upon the basis of 20,000 shares of $5 each, of which Tucson takes 5000 shares, or $25,000, thus placing $40,000 in subscription and bonds at the disposal of Mr. Mason, who subscribes the rest of the stock, namely, 15,000 shares. The capacity of the smelter is 60 tons a day. The smelter is to be close upon the junction of the railroads, and the company will buy all sorts of ore, in lots from 50 pounds and upward. These facts we gather from local papers.

YAVAPAI COUNTY.

HIDDEN TREASURE.—Some good ore has been found at a depth of some 300 feet. It is evident, from all experiments made on Turkey Creek, that the great ore-bodies of the district are not found until a depth of from 200 to 300 feet is attained. Surface workings show that the ore is scattered all through the veins; but, as above stated, when a proper depth is attained, the ore becomes concentrated in solid bodies and of a richness which justifies the outlay necessary in sinking. The company's mill will probably start up shortly.

CALIFORNIA.

MONO COUNTY.

CARBONATE.—McLaughlin & Co. are working this mine situated at Benton. They have developed a fine prospect. The ledge improves in quality and quantity as depth is reached.

PLUMAS COUNTY—GREENVILLE DISTRICT.

GOLD STRIPE.—According to the *Bulletin*, work has been stopped at the mine. The mill will continue to run but a short time, when all the ore now at the dump will be worked up. It is reported that there is no ore in sight in the mine, and that no prospecting will be done unless the shareholders furnish the money.

SIERRA COUNTY.

A prospecting company has been formed in Grass Valley, and it is its intention to keep experienced miners on the road all the time; these experts to prospect for mines and examine mines and report on them. Same parties have started out for a trip through Sierra County.

IDAHO.—The mine is improving, and some good ore has been taken from the bottom of the shaft below the 14-foot level.

PEABODY.—The company has leased its mine for two years, and every thing is now getting into order for work, which will be commenced as soon as water can be had.

CANADA.

PROVINCE OF NOVA SCOTIA.

OXFORD.—It is reported that the property at East Chezzetcook, east of the gold mines of this company, has been purchased by the Oxford for $20,000.

COLORADO.

CHAFFEE COUNTY.

One of the most important elements affecting the prosperity of the Monarch Mining District is the completion of the extension to Garfield of the Maysville branch of the Denver & Rio Grande Railroad.

CLEAR CREEK COUNTY.

Following is a statement of ore-shipments from Georgetown during the month of September:

Shipped from	Tons.	Value in dollars.
Boston & Colorado Works	291	$28,029
Silver Plume Sampling-Works	210	19,800
Miners' Smelting Company	110	12,100
Morris & Noone	222	27,350
G. W. Hall & Co.	15	4,270
Lawson and Silver Creek		
Total	848	$91,810

Besides the above amounts, the Moline Tunnel Company has been shipping from its side-track a short distance below the depot sixty tons a day to the concentrating mill at Lawson.

MICHIGAN.—This property has lately been purchased by a gentleman from New Orleans, at an outlay of a few hundred dollars, and after the expenditure of a few hundred more has developed a value of many thousands. Tests recently made gave of yellow copper $131.65 and of gray copper $111.80 to the ton, and the average of the whole four-foot streak returned $42.80 to the ton.

MOUNTAIN CITY.—This lode at the head of Spring Gulch is down 160 feet. Heretofore, the ore has been greatly scattered, but is now getting more and more compact. Over one inch of solid gray copper, together with 10 inches of galena, with copper and iron pyrites, is now in the shaft. Mill-runs have been had at Black Hawk showing 266 ounces in silver. Shipments will be made weekly.

PERKINS TUNNEL.—This lode on Spring Gulch is driving on a 100-foot contract. At 70 feet in depth, the tunnel is showing up finely. Streaks and bunches of gray copper, with iron and copper pyrites are fast coming in as depth is gained. The gold quartz on the foot-wall remains in place. Nuggets and wires of fine gold are found in the seams. With 100 feet of development, there is no doubt but that this mine will be a steady producer of ore in paying quantities.

RED ELEPHANT.—The properties of this company, which consist of the White, two claims aggregating 3000 feet, Boulder Nest, 1500 feet, and the Free America, 1500 feet, are reported to be in a flourishing condition.

GILPIN COUNTY.

COLUMBIA.—This enterprise began operations about a year ago. The tunnel has been driven since that time 600 feet from the tunnel entrance under Quartz Hill. Situate as it is above Quartz Hill tunnel and below the Central City tunnel, it will be the means of opening up and draining a large number of veins. Several veins have been cut, among them a lode abandoned some years ago, where the tunnel is connected with a shaft sunk to a depth of 110 feet, which affords splendid ventilation to the tunnel. On the foot-wall of the Argo, was found quite a streak of mineral, but of too low grade to be made profitable at the present rates charged for treatment of refractory ores. In and near the breast of the tunnel, two lodes have been struck, the Argo and Vedette, both of which are patented properties. At this point and along the back of the tunnel, there is a large wide crevice which carries considerable mineral. The promoters and owners of the tunnel have ample dumpage ground below the mouth of the tunnel in the gulch to dump waste material. Good headway is made in the tunnel breast, the ground being easily broken. Last month, the tunnel was driven by two shifts, three men on a shift, 67·7 feet in twenty days, at a cost of $4.70 per foot. One man will break enough crevice-matter in one shift to keep two men tramming.

MINERS' WORKS.—The new McNair furnace at these works in Golden is reported by the *Globe* to be a success. A test run made recently treated 53 tons and 1400 pounds of ore more than the other furnace, with 48 tons less fuel. This company has the exclusive right to use this furnace in Colorado, and it is its intention to change all old furnaces for this kind as soon as possible.

REPUBLIC GOLD MINING COMPANY.—In the case of this company, the property of which is situated on the Pewabic Lode, Russell District, where the end-lines of the location were not parallel, in comformity with law, the Secretary of the Interior has decided that the location shall be accepted as it now stands.

FREMONT COUNTY.

ROYAL GORGE SMELTER.—This smelter, located near Cañon City, with two Hall & White stacks, and a nominal capacity of 100 tons a day, gives employ-

Digitized by Google

ment to sixty hands, and does much to sustain the business character of the town. It has, however, been seriously hampered for want of capital to carry heavy stocks that would enable it to compete with other places in the purchase of ores. This is now to be remedied. The smelter has been cleaning up, and on the 26th blew out entirely, with all stock worked up. It will open on the 15th of October with a large backing of Pittsburg capital, which will enable it to take a place among the strongest works of its kind in the country.

ROCKY MOUNTAIN MINE DEVELOPING COMPANY.—This organization, owning the Green Mountain copper mine, seven miles south of Parkdale, and representing Chicago capital, broke ground for its new works on the 25th of last month. The smelter will be located about half a mile below the town, on the river-bank. It will employ hydraulic power, but will also be rigged with steam for emergencies. Most of the plant is already at Cañon, and the work will be pushed without delay. It will have one blast-furnace, with a capacity of 60 tons a day, and the first efforts will be confined solely to the treatment of the company's own ores from the Green Mountain mine; but there is a project of indefinite enlargement as time and capital serve, and the ultimate purpose is to secure the great facilities of Cañon in the way of cheap fuel, cheap flux, and cheap power, to become extensive smelters of copper ores. The furnace is one of Rankin, Brayton & Co.'s stacks, with sufficient engine and crusher capacity to run three additional furnaces. The company has 4500 feet on a very wide lode, carrying oxides and sulphurets, with from 2 to 3 ounces of silver and half an ounce of gold, and from 10 to 16 per cent of copper. Work will be confined to smelting for matte for the present. The mine is opened by a main shaft 100 feet deep, and a winze below that level of 45 feet, the latter in ore. On a distance of 1000 feet, there are 13 test pits, one of them being 45 and the other 40 feet deep. The president is Mr. Wilbur K. Johnson, of Chicago; the general manager, W. E. Johnson; the secretary, Orson G. Stanley, who is now in this city; and the treasurer, J. W. Harrison, of St. Louis. The capital is $3,000,000. The company proposes to do custom-work in the future.

GUNNISON COUNTY.

RICHMOND.—This mine has been sold for $40,000. Regular shipments will be made. The developments consist of shaft, 100 feet, and tunnel; pay-streak, three feet; mill-runs, 750 ounces.

LAKE COUNTY.

ARKANSAS VALLEY SMELTER.—This company has all five of its furnaces in blast. The establishment is turning out about three car-loads, thirty-three tons, of bullion a day. The product of the works is sent to the Kansas City refinery.

CHRYSOLITE.—Exploration-work from the *All Right No. 2 shaft, situated* northwest of the company's office buildings, has been resumed. The shaft has a depth of about one hundredfeet, and discloses a large body of iron. Upon this, drifts are now driving to the east and north, and upward of one hundred feet of drifting has been done. So far no pay ore has been found, but the exploration-work discloses some fine iron ore. Work on the "Iron" incline has been nearly suspended. In the absence of a suitable pump, it has been found impossible to handle the water, and in consequence the advance of the incline is delayed. A large Cameron pump is now on its way from New York, and is expected here in a few days.

DOUBLE DECKER.—This mine, on Yankee Hill, just this side of the Adlaide, promises to become again a producer of rich ore, having recently disclosed very high grade chloride. For six months or more past, the mine has been worked on a lease by Colonel Rush Field and others. Until within the past few days, the results of the work done by these parties were any thing but satisfactory, and it is doubtful if persons could be found in Leadville, that, under all the discouraging circumstances encountered by Mr. Field, would have continued with the same energy and persistency that he has displayed. On last Saturday, a seam of ocherish mineral was struck, which on close inspection showed chlorides of silver. The streak was followed up and soon improved in strength and value, until, at the present time, an eighteen-inch body of ore has been opened in which the occurrence of lumps of horn-silver is very frequent, while the entire mass is impregnated with bromide and chloride of silver. About three tons of this mineral have been hoisted to the surface, from which assays have been obtained ranging from 97 to 747 ounces to the ton. This does not include assays of the higher grade of ores. A shipment will be made to the smelters in a few days.

GERTRUDE.—The strike in this mine, adjacent to the Venture lode, in the Little Frying Pan District, promises to be quite important. The vein is identically the same as the one opened in the Venture, and had previously been explored by a number of shafts. On account of the difficulty encountered by the large flow of water, it has been determined to drive a cross-cut tunnel to intersect the vein. The work was begun during the early spring, and about ten days ago struck the vein at a distance of 210 feet from the portals of the tunnel, and at about seventy-five feet below the surface. A level was next started on the vein to the northward, and at fourteen feet from the tunnel encountered an ore-chimney which has since been penetrated for a distance of twenty feet, showing a three-foot face of mineral the entire height of the drift, giving an average assay of 129 ounces in silver to the ton; while assays have been obtained running as high as 221 ounces. The northern end-line of the claim is still 200 feet distant. Considerable ore has already been extracted, and shipments will be commenced shortly.

IRON SILVER.—The California Gulch properties of this company are doing well, the Stone mine maintaining its regular production of two hundred and fifty tons of ore a day. The lessees on the Rock mine are shipping about twenty tons daily. The incline on the Stone claim, which was driven some years ago, and not given enough pitch, is to be rebuilt. The incline is about four hundred feet in length. A winze is sinking to determine the depth of the contact, in order to ascertain the correct pitch to be given the new incline. No. 5 Stone shaft, which was recently supplied with hoisting machinery, is doing well and yielding a large amount of ore. The shaft has been connected with ore-bodies left beyond the face of the old Rock incline, by a drift. At the Moyer shaft, a second large boiler is getting into position. A building for an engine-house is also going up 180 feet east of the shaft. The seventy horse-power engine formerly in use at the Iron mine incline will be placed in position here, and will be connected with two drums. The water in the Moyer shaft has lately decreased to a considerable extent, and the sinking of the shaft was again resumed.

MAID OF ERIN.—A shipment of fifty tons of ore to the Elgin smelter showed that the mineral ran 140 ounces in silver to the ton, and contained fifty-nine per cent in lead. Pending the decision of Secretary Teller, the mine is doing nothing.

MORNING STAR.—It is said that the Lower Waterloo mine, of this group, contains a seam of ore from one to eight inches in thickness, averaging 797 ounces in silver to the ton, and carrying twenty-four per cent of lead. A wagon-load shipped to Cumming & Finn's smelter the other day netted over three thousand dollars.

NEW ENGLAND.—The Ohio Bonanza tunnel, situated near the California Gulch, is worked and extends good promises of developing an ore-body. The property is owned by the New England Company. The tunnel is in over 200 feet, and is reported showing a well-defined vein, assaying from six to seven ounces in silver and two tenths ounces in gold to the ton.

OPULENT.—That portion of the mine on Little Ellen Hill not in conflict with other properties is working again.

PRINTER BOY.—This mine, situated opposite Oro City, is to be worked again. A contract has been let to put up a hoisting-engine, boilers on the property, and also a large steam-pump. Work is to be commenced in the lower shaft of the claim. The property has already produced largely, and only fell off in production when the depth precluded further operations on account of the absence of proper machinery for working the mine and handling the water.

RUBY.—So far, the mine has shipped but limited quantities of ore, all efforts having been concentrated in the attempt to more thoroughly explore and develop the mine's resources. This work is now nearly accomplished. The property will be incorporated some time in October, the company to be known as the Savannah Mining Company. Its capital will be moderate, probably not exceeding fifty thousand shares.

SILVER CORD.—Prospect-work has been started in a number of places. The extension of the main incline (No. 2) has been resumed, also the driving of the south level, in each of which machine drills are employed. As a consequence, good headway is made. The south gold incline, driven for some time past on a barren crevice, has opened a large body of medium-grade ore, through which is dispersed some fine shipping mineral. The crevice disclosing this ore-body is nearly parallel with the Gold Ore chute, and a short distance to the south. It gives indications of developing a new and profitable source of ore supply to the mine. The Gold Ore chute is holding out about the same as heretofore. The ore, to appearance, is a little lower in lead, consisting more of ocher, but may have improved in a proportionate degree in gold. The No. 3 ore-chute shows no noticeable change. The breast of the ore-chute is evidently composed of as good material as at any time in the past, while the ore-body shows no diminution in strength or size. The product for September is estimated at about 3600 tons. The work of reconstructing and repairing the plant destroyed by fire several months ago will soon be completed.

PITKIN COUNTY.

OAKLAND CONSOLIDATED.—A note, published by the Aspen *Rocky Mountain Sun* states that this company will not be responsible for any work done on the Oakland No. 2 mine, nor for any debts contracted, unless authorized by the superintendent, L. J. W. Herrick.

SPAR.—The mine is worked steadily. Ten tons of ore daily are packed to the smelter, averaging $200 per ton in silver. A 1000-foot tramway is to be built from the workings, upon which to chute the ore to the foot of the mountain to a point where it can be teamed to the smelter, when the shipments will be largely increased.

PUEBLO COUNTY.

PUEBLO OIL COMPANY.—The result of the recent meeting mentioned in our last issue has been the organization of a company with the above name, with a capital stock of $50,000. Work will be commenced at once, and if the sinking of one well does not find oil, another will be sunk.

SUMMIT COUNTY.

ROBINSON.—The Leadville *Herald* says that eight car-loads or eighty tons of ore were shipped September 22d. September 24th, the shipments amounted to only twenty-five tons. The mine, judging from what can be learned in conversation with parties familiar with its appearance, is not looking as well as might be desired.

DAKOTA.

ESTRELLA DEL NORTE.—The superintendent reports that the result of this season's work so far has turned out beyond all expectations. The force-pumps which are to convey the water to the higher bars will soon be in position; and when they are up, the product of gold will be greatly increased.

ETTA.—Work is now in progress at this tin mine.

FATHER DE SMET.—The superintendent writes, under date of September 15th, as follows: The Golden Gate south header made its usual progress last week, the face showing as well as ever. East cross-cut, third level, continues in ore, though mixed up some with slate, but it is a good average. We are now in about 17 feet in this body, and the chances for developing a considerable amount of ore in this level seem very favorable. The rest of the mine shows about as usual, plenty of ore being in sight, the cut being very low grade in quality. I am compelled to draw for $25,000 to-day, to meet last month's expenses, which were very heavy, owing to the large bills coming in for winter supplies. I think the September account will about finish these bills up, and enable us hereafter to get along with much less expense for several months to come, every thing running along well. The report for the week ended September 22d shows: Ore extracted from first level, 700 tons; second level, 800 tons; third level, 485 tons. Ore milled, 1975 tons. Golden Gate east cross-cut, third level, in 62 feet; Golden Gate, south header, second level, in 42 feet. I herewith inclose you express company's receipt for bar No. 167, containing 758 1-5 ounces gold, the result of run of mill for the first half of September. This is averaging so far a little better than the previous month. Every thing is going ahead and looking about as usual. The mill is running along smoothly and doing good work.

GRIZZLY BEAR.—The ore which is to be worked by the new stamp-mill is taken from the recent rich strike. On this streak, a tunnel has been driven eastward from the old open cut about twenty feet, and another westward sixty feet. This tunnel is about forty feet below the surface. Another ditch has been surveyed to bring water from a small branch of the gulch, in order that the whole twenty stamps may be brought into service.

STAND-BY.—Every thing will be in readiness for starting the water into the ditch early in October, and a number of the stamps will be employed upon ore from the Stand-by mine. This ore will be extracted from the old open cut and from a shaft which is now down to a depth of twenty feet. In this shaft, a streak of rich rock has been found.

IDAHO.

The Mayflower, Jay Gould, Narrow Gauge, and other mines whose ores carry 50 per cent of lead or more, are making arrangements to ship either to Omaha, Denver, Salt Lake, Melrose, or San Francisco, since the Philadelphia Smelting Company declines to buy their ore.

ALTURAS GOLD HILL.—The working force has been increased. A vein of rich ore about about three and a half feet in width has been struck and stripped for a length of 35 feet along the vein. There have been recently extracted about 200 tons of this ore that will yield an average of $100 per ton.

COLUMBIA & BEAVER.—The mill has not only been running satisfactorily, but has been doing better than was expected.

ORADO.—This company has purchased the Byron and Baltic mines, in Mineral Hill Mining District, Wood River. The mines are on the great vein or mother lode of the district, cropping out bodily from four to five feet wide, between a lime and granite formation, lime for the foot and granite for the hanging-walls. They were located in 1881.

PHILADELPHIA SMELTING COMPANY.—The order recently given regarding the purchasing of ores applies only to the ores which go very high in lead. The company will continue to buy all those that are low grade in lead.

DOUGLASS.—At the sale of this copper company's stock, delinquent under the fourth assessment of twenty-five cents per share, held at Bangor recently, nearly the entire block, comprising some 35,600 shares, was purchased by Hon. F. M. Laughton for the amount of the assessment.

MICHIGAN.

Explorations on section 10, T. 34, R. 34, have been suspended on account of "wet ground." The intention is to resume work again as soon as the weather is cold enough to freeze up the surface water accumulations.

A project is said to be on foot for the erection of a concentrating mill near Republic, at some point where the water-power can be had from the Michigamme River.

BRIER HILL.—Local papers report the stoppage of work on account of exhaustion of the ore-deposits.

EAST VULCAN.—A new shaft was started recently for the purpose of tapping the new vein.

INDIANA.—After a five weeks' idleness, work has been resumed with favorable results.

Digitized by Google

IRON HILL.—A hard blue hematite carrying nearly 60 per cent of metallic iron was taken out of the shaft sinking by this company.

NEGAUNEE CONCENTRATING COMPANY.—The mill has been closed down for the winter. The cause of this suspension is not yet known. Some reports state, however, that it has been owing to a disagreement among the stockholders.

PENN.—The company is putting down a test shaft in the hill between the Norway and Cyclops mines.

ROPES.—The mill is now running on rock taken from a new shaft, 100 feet east of the Curry where the rock milled in the first run was obtained. The management desires to prove by actual test the character of the vein at this point, and will mill 100 tons of rock mined there to that end. This shaft is down some 12 feet, the lode having a width of six feet, and the vein-matter gives promise of making a very satisfactory showing under treatment, several assays indicating that it is quite highly charged with the precious metals. Mining work is also going on in the Curry shaft, where some extremely rich rock is taken out, the free gold in it being visible to the naked eye.

MONTANA.

SILVER BOW COUNTY.

MARGARATH.—An important strike is reported in this mine, which lies immediately east of the Colusa. The shaft is sinking in vein-matter which shows a width of fifty feet at the surface. At a depth of 37 feet, an 18-inch pay-streak has been struck. The ore is black sulphurets carrying native silver, and assays from 120 to 200 ounces.

MONTANA COPPER COMPANY.—The numerous inquiries received by this company as to the amount of production of its smelting-works have induced Mr. Rauuheim to state the following through the Butte *Inter-Mountain:* Owing to the recent depression of the copper market in this country, it was formerly thought not advisable to publish figures, the copper produced by this company being consumed by home brass manufactories. Since September, 1882, all the mattes produced by this company have been exported to England and contracts have been made in Europe lately for a long time to come, therefore there is no reason for withholding figures from the public. During the last twelve months, ended September 1st, 1883, the Colusa Smelting-Works shipped for export 8100 tons, averaging sixty-five per cent copper and fifty-five ounces silver per ton. Should a reduction of freight rates and fuel be granted by the rival railroads, the Montana Copper Company intends to erect an additional blast-furnace, having a daily capacity of 100 tons, thus doubling the present production.

WILLIAMS SMELTER.—The capacity of these works is to be increased by three stacks. The castings for two of them, which will be erected this fall, have already been shipped. The third stack will not be built until spring. These improvements were made as the result of the recent visit of Senator Hill and Mr. Richard Pierce, of the Argo Works, to Butte, the magnitude, permanence, and richness of whose mines deeply impressed them with the great future in store for the district. The amount of Butte ore in a crude state at the Argo Works is about 3000 tons, all of which was shipped from the Williams smelter in addition to its matte shipments.

NEVADA.

ESMERALDA COUNTY.

ENTERPRISE.—Operations have been resumed on this mine, the first westerly extension of the Mount Cory mine. This property has favorable prospects. It is intended to extend the present tunnel, which is in about 350 feet, to the ledge.

STATE LINE.—According to Nevada papers, the judgment of Tallman & Co. for $20,000 against this company has been set aside. It is stated that the company has been waiting the termination of this suit to resume work.

EUREKA COUNTY.

ALBION.—The *Sentinel* states that the mine is economically prospected, and the outlook for it is encouraging. The east rise is yielding ore in paying quantities, and some rich ore has been discovered in a rise from the June chamber. It was found about 150 feet from the A. C. line, and is making strong in Albion ground, in a northwesterly direction. The prospecting tunnel, continued from one of the flue-dust tunnels, cut a large open crevice or cave a few days ago, which goes to show that open and better ground is to be expected from now on. A farther distance of 60 feet will bring the tunnel to a point over the east uprise, where the chances for striking an ore-body have always been considered good.

ELDORADO CONSOLIDATED.—A streak of high-grade ore has been discovered in the No. 2 mine 120 feet below the level of the Eureka Tunnel and Eldorado Consolidated properties. It assays $190 per ton.

LINCOLN COUNTY.

RAYMOND & ELY.—All the machinery and company's lands and improvements at Bullionville are advertised for sale. Application may be made to J. V. Keeley, agent for Lazard Frères, San Francisco.

NYE COUNTY.

TWO G.—Work has been resumed at this mine, which has been closed down for three years. The mine has not been prospected lower than 400 feet. At this depth, water was encountered and work was stopped, and there was no machinery to handle it. On this level, the ledge was followed in a direction nearly north and south about a mile, the vein holding out along that length and going down all the while. A great deal of prospect-work has been done, generally with profitable results. The present company has had excellent success in mining and milling. It roasts and crushes the ore, instead of smelting it, as was formerly done, and works it up to 92 per cent of the pulp-assay; whereas, in the smelters, it was not worked up to more than 61 or 62 per cent. The twenty-stamp mill crushes 23 tons a day. The company is working for the present in the 300 level. It has put in a pump, and the water it uses is taken from the 400 level. It has had no occasion yet to try to drain the water-level, but believes that, when it needs to, there will be no great trouble in doing so. Since starting up the mill, it has turned out an average of about $500 very fine bullion per day. The run of the last thirty-five days was over $17,000, with two or three thousand dollars of amalgam remaining over. The present company, owing to its closer milling, can utilize a great mass of ore in the mine as well as a good deal on the dump that the former company did not succeed in working at a profit.

STOREY COUNTY—COMSTOCK LODE.

IMPERIAL.—The furnaces have been fully fired up, and the shriek of the whistle heard for the first time in nearly two years.

NEWFOUNDLAND.

A new lead and silver mine has been opened near Little Placentia, under the management of Mr. F. Ellershausen, who purchased the claim from the discoverers for £4500 sterling. Some of the richest specimens yielded, on analysis, 300 ounces of silver to the ton. It is considered a most promising mine. A large number of men are employed in working it.

BETTS COVE.—A considerable amount of ore has been extracted this year.

LITTLE BAY.—At the copper mine, nearly five hundred men are at work. The yield of the mine is in every way satisfactory.

NEW MEXICO.

GRANT COUNTY.

There are about twenty-five men employed in placer mining in Piños Altos, making a fair living. In many instances, the dirt is carried several miles to water. The arrastras are running permanently on good ore from mines in the vicinity.

BLACK PRINCE.—At the bottom of the fifty-foot shaft, 20 inches of good milling ore are found. The surface croppings plainly indicate great value.

COLUMBIA.—The shaft is 70 feet in depth, and shows from the surface to the bottom a continous and well-defined vein of ore having a milling value of $125 per ton. The vein occurs in a granite rock, and runs north of east and south of west, and is almost vertical in its dip. The mineral consists of chlorides and sulphurets of silver associated with heavy-spar and talcose matter which constitutes the gangue of the vein.

GLADSTONE.—At present, this is but a mere pit as far as developments go; but when the owners prosecute the work now contemplated, their labors will be rewarded by an abundance of fair milling ore.

OLD MAN.—The developments made show most satisfactory results. An important strike was recently made in the deep shaft.

SOCORRO COUNTY.

A number of parties are about six miles east of Socorro, working the coal-banks and marble quarries, which show well. A large bed of tripoli has been discovered; in the same neighborhood and not far distant, some excellent fire-clay has been brought to light. But few mines are developing in the Socorro Mountains; but those that are worked, notably the Alabama, Reserve, Morning Star, and others, are all looking well. The Merritt is idle on account of a disagreement with the owners of the stamp-mills.

SILVER PEG GROUP.—This is considered one of the most promising properties in the entire Magdalena range. The group comprises the Doubtful, Black Crook, Gertrude, and Commonwealth locations, and is located on the west side of the mountains, adjacent to water, of easy access for wagons and but three fourths of a mile from the smelter. It shows large quantities of galena running well in silver. The property is said to be for sale, and can be purchased for $20,000.

NEW YORK.

A correspondent of the *Evening Post* writes from Northville that the discovery of gold has caused some excitement. One of the mines is situated on the south side of a hill rising steeply from the Sacondaga, in a ledge of soft, shaly rock, easily disintegrated. There was gold there, to be sure, but it was much mixed with the sulphuret of iron, a peculiarity of most of the Adirondack ores. The second mine was on the opposite side of the hill range, and had been opened to a depth of about thirty feet, and then abandoned. At Benson Center, ten miles west, there are two mines in full operation, one worked by a local company, the other by Amsterdam (N. Y.) capitalists. The material of these mines is sand, which is worked by being reduced to powder in a "pulverizer," the gold being extracted in the ordinary way. These companies are said to be taking gold in paying quantities, although they are quite reticent about the matter.

NORTH CAROLINA.

SILVER VALLEY.—This company has ordered a concentrating plant to be connected with its twenty-stamp mill. It is stated that this is a step the company should have taken long ago, as it has been losing many valuable metals in the tailings which it now purposes saving.

PENNSYLVANIA.

Mr. John Eyerman, of Easton, sends us the following notes of interest:

FRIEDENSVILLE ZINC MINES.—All underground work at this mine has ceased. A new shaft is sinking about 150 yards from the old one. It is expected to strike the ore at a depth of about 400 feet. Galleries will be extended from the new shaft to the old workings, thus connecting the company's different mines. When the shaft is completed, the company proposes to remove the famous West engine, which has a capacity of 550 horse-power, from the old Ueberroth mine to the new shaft, thus doing away with all steam-pumps, which are hardly applicable for so great a distance on account of the condensation of the steam in the cold air. The new shaft will be 10 by 15 feet, and will probably be completed in five months. The sand collected by the old company is "buddled," and produces from 20 to 25 per cent of zinc. There are acres of this sand around the mines which was regarded by the old company as worthless. The electric lights will be introduced into the mines.

SUNBURY LEAD MINES.—On the 13th of September, a large number of persons, among whom were many stockholders, crowded the furnace-room of the Susquehanna Mining and Smelting Company, at Sunbury, to witness the first tapping of the furnace. At half-past six P.M., the furnace was charged with 3000 pounds of lead ore (galena, etc.), and tapped at forty-five minutes past nine, turning out 1600 pounds of nearly pure metal. Five to six hours is the usual smelting time. The furnace, which was built by Messrs. Holliday & Kidney, will work 3000 pounds of ore in three hours. The ore used for the first charge was washed from the fine dirt taken from the mine. The lump ore, five times richer, can not yet be handled, as the proper reducing machinery has not arrived. It is said that the ore will be concentrated to 60 per cent. The principal men in the company are Bostonians.

CORUNDUM IN LEHIGH COUNTY.—Early in the year 1882, while plowing, a farmer threw out some crystallized substance, which, upon examination, proved to be corundum. The largest crystal had a length of eight inches. Some months ago, two gentlemen from Allentown leased a plot of land adjoining the one on which the crystals had been found, and began sinking shafts on the high land, about 200 yards from the original locality. The shafts vary in depth from 30 to 5 feet. At the time of my visit on the 27th of September, five shafts were opened, and a considerable quantity of corundum taken out. The shaft farthest south seems to produce the best specimens. It is down 18 feet, and is connected by a gallery with the other shaft. As yet, no specimens large enough for working have been taken out; but it is expected that they will strike larger specimens shortly. In some of them, menaccanite, an ore of titanium and iron, is found coating the crystals as well as disseminated through them. The outlook is certainly very favorable, and it is hoped that these enterprising gentlemen may strike the vein containing large specimens.

THE IRON REGION OF NORTHAMPTON COUNTY.—All the iron mines of the Saucon Iron Company have ceased work. For some months, they have only been worked half their capacity. One of the stacks at the company's works at Hellertown is blowing out, the other one having been idle several months. It is reported that the furnaces will be sold. Many iron mines in Lehigh County have been idle for several months.

THE CHESTER COUNTY LEAD REGION.—In a recent trip through the Chester County lead region, I noticed that most of the engine-houses are falling to the ground and the machinery rusting from exposure to the dampness. If these mines were operated, what splendid railroad facilities the company would have, a branch of the Pennsylvania & Schuylkill Valley Railroad running within ten feet of the Charlestown mine and within a short distance of the others. The Pennypacker mine is filled with water to the top of the shaft. There is a considerable quantity of lead and zinc on the waste-heaps.

UTAH.

IRON COUNTY.

IRON MANUFACTURING COMPANY.—The mining claims owned by this company, recently incorporated with a capital of $200,000, with the privilege of increasing it to $2,000,000, are known as the Duncan No. 1, Blomont, Chesapeake, Excelsior, Pot Metal, and Black Magnetic, in all about 120 acres, located in the Pinto Mining District, also, the Desert Mound, in Iron Springs District, and other mining claims in this county. The principal place of business is Salt Lake City.

SUMMIT COUNTY.

BON HOMME.—This company has been incorporated with a capital stock of $300,000. The following properties belong to the corporation: The Lucky Boy, Old Observation, Protection, Park View, Springfield, Nevada, Red Boy, Bevan, Sample, Boston, Crown Point, Garden City, Davenport, Henry Clay, Alameda, and Protector, situated in Uintah Mining District.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Oct. 5.

The mining market this week has been simply a brokers' market, and the dealings, or most of them, have been confined to the fancy low-priced stocks. Of these, Eastern Oregon, Decatur, Elko, and Sonora take the lead, while Sutro Tunnel and Robinson also show very large transactions. There is no change in the price of these stocks worthy of notice. The stock of the Harlem Mining and Milling Company suffered a considerable raid, and the price was forced down to a low figure. The transactions were very heavy, the stock being the most active in the market. The total number of shares sold aggregates 183,363 shares, as against 107,890 last week.

The Comstock shares were quiet at steady prices. California was quiet and weak, selling from 15@8@14c. Consolidated Virginia was moderately dealt in and was steady, selling from 39@44c. Sierra Nevada was strong, under a small business, selling from $3.40@$4. Union Consolidated was irregular, with a small business; it sold from $4@$4.75@$4.25. Mexican was quiet and steady at $2.25@$2.50. Ophir sold at $3.25; Savage at $2; Yellow Jacket at $3.25, and Best & Belcher at $3.10. Sutro Tunnel was active and irregular, selling from 19@17@18c.

The Leadville stocks were but moderately dealt in, and were steady. Amie was quiet and a little weak, selling from 16@18c. Chrysolite was moderately dealt in, and was also a little weak; it sold from $1.25@$1.15. Dunkin sold at 25c. and Breece at 19c. Iron Silver was quiet and strong, selling from $2.90@$3.10. Leadville was also quiet at steady prices; it s old from 40@49c. Little Chief was quiet and a little weak, selling from 63@58c. Little Pittsburg sold from 64@65c., with a very small business.

The Bodie stocks were quiet and weak. Bodie Consolidated was fairly dealt in at weak prices; it sold from 58@50c. Bulwer was also weak, under a small business, selling from 57@46c. Standard was quiet and strong, selling from $5.75@$6.25. Bechtel sold at 5c.

The Tuscarora stocks were very quiet at steady prices. Grand Prize was quiet and steady at 15@22c. Belle Isle sold from 31@28c., with a small business. Navajo was quiet at $2.75. North Belle Isle was quiet and steady at 46@41@45c. Elko Consolidated was very actively dealt in and was a little weak; it sold from 9@7c.

In the miscellaneous list, Alice was strong, with a small business, selling from $2.70@2.75. Bassick sold at $9. Eureka Consolidated was quiet and steady, selling at $6.25@$6.13. Hall-Anderson was quiet at steady prices, selling from $1.15@$1.10. Horn-Silver was moderately dealt in and was steady; it sold from $7@$7.13. Northern Belle was quiet and steady, selling from $5.50@$5.75. Robinson Consolidated was fairly dealt in at irregular prices; it sold from 36@40@38c. Sierra Grande was strong, with a small business, selling from 83@$1.10.

Barcelona was quiet and irregular, selling from 36@33@34c. Caledonia sold at 35c. under a small business. Central Arizona was quiet and steady at 33@30c. Decatur was very actively dealt in at irregular prices; it sold from 3@5@4c. Eastern Oregon was also very actively dealt in and was steady; it sold from 49@47c. Harlem was very active and weak, selling from 97@70@76c. Rappahannock was irregular, with a small business, selling from 6@9@7c. Red Elephant was quiet and steady at 5@6c. Sonora Consolidated was actively dealt in at about steady prices; it sold from 28@25c.

MEETINGS.

The Findley Gold Mining Company, No. 70 Broadway, New York City. Special meeting of stockholders, October 23d, at three o'clock P.M.

The Hampshire & Baltimore Coal Company, No. 18 Broadway, New York City. Annual meeting of stockholders and election of trustees, October 18th, from twelve o'clock M. to one o'clock P.M.

The Mamie R. Gold and Silver Mining Company, Windsor Hotel, Fifth avenue and Fifty-sixth street, New York City. Annual meeting of stockholders and election of trustees, October 6th, at half-past one o'clock P.M.

The Rara Avis Gold and Silver Mining Company, Stock Exchange, Room 30, Philadelphia, Pa. Special meeting of stockholders for the purpose of increasing the capital stock from $2,000,000 to $4,000,000, November 15th.

DIVIDENDS.

The Idaho Mining Company, of California, has declared a dividend of $1 per share, payable in San Francisco.

The Leadville Consolidated Mining Company, of Colorado, has declared a dividend of five cents per share, payable October 15th, 1883. Transfer-books close October 9th and reopen October 17th.

The Plymouth Consolidated Gold Mining Company, of California, has declared a dividend of fifty cents per share, payable immediately.

The Standard Consolidated Mining Company, of California, has declared a dividend of twenty-five cents per share, payable October 12th.

The Union Coal Mining Company, of Maryland, has declared a dividend of two and a half per cent upon its capital stock, payable October 8th.

PIPE LINE CERTIFICATES.

The petroleum market this week has been very active, but prices have declined from the opening last Saturday, closing weak to-day, as will be seen by the table below.

On Monday last, the news from the oil-fields was "bullish," several wells being reported dry. The news helped the market, but a continual selling caused a gradual decline. Tuesday, the market was very active, liberal purchases being made by the "shorts." There was an advance at one time, but the market gradually weakened. Wednesday and Thursday, there were very heavy dealings, with a declining market. Reports that two new wells near the border side of the Balltown belt had come in, one dry and the other a small producer, influenced a slight rally, but the close found the market in an unsettled condition. To-day, the market declined slowly, and closed in an unsettled condition.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

		Opening.	Highest.	Lowest.	Closing.	Sales.
Sept.	29	$1.15⅞	$1.16¼	$1.15¼	$1.15½	1,619,000
Oct.	1	1.15⅝	1.15⅞	1.14⅜	1.14⅝	2,168,000
	2	1.14⅝	1.15⅜	1.13⅝	1.14	3,772,000
	3	1.13⅜	1.14⅜	1.13¼	1.13⅜	3,330,000
	4	1.13⅜	1.13⅞	1.12⅝	1.13¾	3,464,000
	5	1.13¾	1.13¾	1.12⅜	1.12⅞	3,140,000
Total sales						17,493,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, October 4.

There is but little change to note in the condition of the market for mining stocks the past week. The coppers are firm, and in a few instances a slight advance is noted, but the market continues dull and without any special indication of an increased activity in th near future. The silver stocks are as dull as ever, and it is evident that the public generally has no money or disposition to invest in new ventures with the experience of the past two or three years looking it in the face. Calumet & Hecla holds its price well at $245@$246, with but little stock changing hands. Franklin advanced from $12@$12½, with sales of a small lot at $13, and is quite firm at $12½ bid and none offered. There was a rumor that the Quincy was negotiating for the purchase of this mine, but we hear that it is officially denied. The product for September was 187 tons, against 170 last year, and there is no doubt that the mine is a paying one and can earn a dividend the present year. Quincy sold at $54@$54¼, but there was very little doing in it. The increase in the product last month was about 12 tons, being 336 tons, compared with 325 in 1882 and 317 in 1881. Osceola advanced from $18@$19 on sales of 15 shares. Pewabic declined from $3 (September 21st) to $2½. The reports from the mine are not very encouraging, the September product showing a loss of 23 tons as compared with last year. A sale of 100 shares of Ridge at 62½c. is the only transaction reported of the low-priced stocks. The reports from the Huron mine continue favorable, the September product being 57 tons, against 27 tons last year and 12 tons in September, 1881. $1½ is bid for the stock, and none offered less than $2. No sales reported.

In silver stocks, Bonanza was steady at $1¾, with sales of 500 shares only. Catalpa declined from 35c.@32½c. Crescent sold at 7½c. Harshaw at 50c. Sullivan was quite firm on limited transactions at $⅞@$1. Bowman Silver, sales at 11@13c., assessment paid. Massachusetts & New Mexico, offered at 4c. Dunkin, 25c., ex dividend. Silver Islet advanced from $2½@$3 on good news from the exploring party on the company's lands on Lake Superior. It is reported that a vein of very rich silver-bearing ore twelve inches wide and only eighteen feet below the surface has been struck, assays of which yielded an average of over 5000 ounces to the ton. Should this prove to be a veritable bonanza, the stockholders will find cause for congratulation upon the outlook and prospect of a return for the numerous assessments which they have been called upon for to keep up the enterprise.

3. P.M.—There was nothing doing at the afternoon Boards and prices unchanged. Closing prices: Bonanza, $1½ bid, $1⅞ asked. Calumet & Hecla, $245 bid, $246 asked. Franklin, $12½ bid, $13 asked. Pewabic, $2½ bid, $3 asked. Quincy, $54 asked. Silver Islet sales, $3 and bid.

BULLION MARKET.

* Non-assessable. † The Deadwood has previously paid $275,000 in eleven dividends, and the Terra $75,000. ‡ This company, as the Western, up to December 10th, 1881, paid $1,475,000. Quotations of these stocks will be found in S. F., San Francisco; B., Boston; and P., Philadelphia, tables. E are British companies. ‖ Total number of shares, 500,000; 50,000 shares have never been issued, and are still held by the company. Dividend shares sold, 50,693.

several hundred thousand pounds. The contracts with consumers made earlier in the summer are soon ended, and the period for the purchase of new supplies is drawing near. One of the Arizona mines has contracted for the sale of six months' product, roughly five and a half millions, at 14½c., about three quarters of the quantity going abroad. Quotations for other brands than Lake range between 14¼@14¾c., according to quality, the quantity available being moderate. England cables lower to-day, quoting £62 7s. 6d. for Chili Bars. Business abroad seems depressed.

Tin.—Though quiet, this market is firm at 21c. spot for Straits and Malacca. The shipments from the Straits and from Malacca were, during Septem-

G. Gold. S. Silver. L. Lead. C. Copper. * Non-assessable. † Stocks quoted on S. F. San Francisco; B., Boston; P., Philadelphia. Non-Dividend shares sold, 132,670. Total shares sold, 138,368.

ber, 710 tons to the United States and 350 tons to Great Britain, which received also 900 tons of Australian. London cables to-day £94 10s.

Lead.—During the week, sales aggregating 600 tons, exclusively ordinary and good Western, were made at 4·30@4·32½c., and one lot 4·25c. Negotiations for the sale of several thousand tons of Richmond lead have fallen through, the best bid being, we understand, 4c.

From St. Louis, Messrs. John Wahl & Co. wire us as follows to-day:

The market remains the same — if any thing, a shade weaker. The demand is very moderate, and there is very little doing on account of carnival week. Refined here is held at 4·05c. and Common at 4c.

From Chicago, Messrs. Everett & Post send the following dispatch:

Our market shows signs of weakness. Sales have been made of some four hundred tons of Common and Refined at 4·05c., 4·04c. and 4·02½c. Our market closes quiet with 4c. bid.

Spelter.—The market is quiet and dull. Ordinary Western brings 4⅝c., better grades 4¾c., and such brands as Glendale, preferred for brass making, as high as 5c. Foreign is nominally 5⅛c. There is some talk in Europe of another "syndicate."

Antimony.—With a moderate trade, quotations

remain 10⅛@10¼c. for Cookson's and 9⅛c. for Hallett's.

IRON MARKET REVIEW.

New York, Friday Evening, Oct. 5.

Mr. Edward J. Shriver, Secretary of the Metal Exchange, has compiled the following statement of stocks in bond in the ports of New York, Philadelphia, Boston, Baltimore, and New Orleans on October 1st:

	Jan. 1, 1883. Tons.	Sept. 1, 1883. Tons.	Oct. 1, 1883. Tons.
Pig-iron	6,330	5,261	4,473
Spiegeleisen	4,131	1,467	1,667
Old rails	5,504	2,151	2,151
Scrap-iron	1,384	2,157	1,141
Scrap-steel	456	306	806
New iron rails	6,642	355	481
New steel rails	4,816	121	571
Grand total	29,263	11,818	12,290

American Pig.—The Metal Exchange has the following returns from five furnaces for the month of September:

Grade.	Stocks. Sept. 1.	Stocks. Oct. 1.	Production. Aug.	Production. Sept.
No. 1	9,808	9,345	5,001	6,461
No. 2	7,561	6,682	3,020	2,692
Bess., Forge, and lower grades	32,184	27,676	6,907	7,299
Grade not specified	7,750	7,171	6,606	6,717
Total	57,303	50,874	21,534	23,165

The event of the week has been the reduction in the price of Thomas No. 1 Foundry to $21 from $22, No. 2 being quoted at $20, and Gray Forge at $19. Sales in consequence of this reduction, which we presume simply follows openly the lead taken by others quietly, aggregate 500 tons. Transactions during the week have been on a very moderate scale. We quote No. 1 Foundry, $21@$22.50; No. 2, $19@$20.50, according to quality; and Gray Forge, which is easier, $18@$19.50, all at tide-water. There have been sales of round lots of Bessemer Pig at $20, and Spiegeleisen is dull at $30.12½@$30.50 for 20 per cent. Low grades are dull at $25.

At the Exchange, the following transactions were recorded:

Saturday, 100 tons pig, No. 1, spot, $19.25. Monday, 200 tons American pig, No. 1, January, $20; 100 tons Carbon, No. 1, short notice, $19.25. Tuesday, 300 tons pig, No. 1, January, $20.25. Wednesday, 100 tons Colebrook, No. 1, short notice, $19. Thursday, 100 tons American, No. 1, November, sold at $19.50; 100 tons No. 1, January, $20¼. To-day, 300 tons, No. 1, January, $20.25, and 300 tons, No. 1, February, $20.50.

Scotch Pig.—Nothing has been done, and though arrivals are light and the number of parties importing is steadily diminishing, business is limited.

We quote ex ship and to arrive: Coltness, $22.75@$23; Langloan, $23; Summerlee, $22.50@$23; Dallmellington, $20.50@$21; Eglinton, $20@$20.50; and Glengarnock, $22@$22.50.

At the Exchange, warrants to-day were 47s.

Rails.—Business is very dull, and a number of the mills have no engagements beyond the first of December. It is likely that the most unfavorably situated will have to stop temporarily, unless orders come forward more liberally, and prices are maintained at the present quotation, $37@$37.50 at mill.

Old Rails.—There is very little doing at lower figures. We quote $22.50@$23 for Ts.

Scrap.—Scrap is dull at $22 ex ship.

Philadelphia. October 5.

The break in pig-iron this week is expected to develop considerable activity in the course of the next ten days. No. 1 Thomas iron was reduced in New York to $21, and No. 2 to $19, although the company here has had no instructions to sell at those prices. It s understood that business will be done on that basis. Other companies are preparing to follow suit, and it is probable that a restriction of output will be developed in a short time, because of the impossibility of a number of the furnaces now in operation to make and sell iron at those prices. $22 is still asked and probably will be held to for some of the brands of No. 1, while No. 2 will range from $19 to $20, according to brand. The requirements are large and have been withheld, and it is now probable that they will be presented and filled for the rest of the year. Authorities in pig-iron think that the policy of cutting prices is a wise one, and that it will have a two-fold effect, first to restrict output, and secondly, to induce buyers to purchase. An upward tendency is certainly needed to stimulate trade. The business for the past week has been confined to small lots. No. 2 Foundry is plenty, and the consumption moderate. Gray Forge is unchanged, but is firm at $18 at furnace for best makes. A number of transactions took place at $17.50@$17.

Bessemer iron is without activity. A few thousand tons of Spiegeleisen have been sold at $30.25@$30.50. A great deal could be sold at $30. Muck Bars have sold from $33@$34 for ordinary makes, with $34.50@$35 asked for the best makes. Good Puddled Bars command $34, and orders for the best makes have been refused within a day or two at that figure. Some mills are sold from four to six weeks ahead, and the demand is active.

In manufactured iron, there is still a declining tendency. It is scarcely possible that that drop in foundry can affect forge, as foundry is simply equalizing itself with forge. Refined iron has weakened down to $20 in large lots, though iron has sold all along at 2·10@2·15c.; but the tendency is decidedly to the lower limit. Country mills are taking orders at this price. There is much apprehension as to Western competition, Western iron being delivered in this market at 2c., and it is said that even lower prices have been named.

There is a fairly active demand for nails, for the season, though fewer car-load lots have been sold this week than heretofore. Jobbers are not urgent about filling up, on account of the downward tendency. Quotations, $2.90@$3.

All the sheet mills are busy, stocking up for the winter's consumption, and filling current orders at card rates, 4c.@4½c.

The plate mills report fair inquiry, but less business for the past week. Prices are firm at 2·40@2·50c. for Tank, 3@3·25c. for Shell, and 4@4·25c. for Flange.

No heavy orders for structural iron have been received, but there is plenty of business in sight, which will be placed at the right time at the usual rates.

No new business has been done in steel rails. Quotations, $37@$38. Offers are made below these rates for winter deliveries.

A few thousand tons of old rails in large and small lots have been sold at $24.25 for Bridge Rails and $23.50 for Tees. Cargo Scrap is quoted at $23; Selected, $24@$25.

COAL TRADE REVIEW.

New York, Friday Evening, Oct. 5.

Anthracite.

The anthracite trade has had its sensation this week, and is to-day in a state of considerable excitement, which, so far as we can learn, is not quite warranted by the facts. It became generally known this morning that the Delaware & Hudson Company had "made a cut in prices," and pretty wild stories were afloat as to the extent and character of the reduction. Mr. Dickson, of the Delaware & Hudson Company, informs us that, owing to shortage of cars for shipment of coal Westward, the company had larger quantities of anthracite than usual coming to tide-water, and, to prevent an accumulation, had decided to offer stove and chestnut coal at a lower price to some of its clients. It is reported that the figure is $4.30 for stove, and that it has been offered to commission houses at that figure. So far as this proceeding is concerned, there is nothing startling in it, as a number of New York companies have undoubtedly done the same thing repeatedly during the past month, but they have one and all nominally held to their prices, and have in a quiet way made the best bargain they could, and well-posted buyers have been perfectly well aware of the fact. If the object of the managers of the Delaware & Hudson Company was merely to place a temporary surplus of coal, they have certainly gone at it in a manner likely to defeat their own end. The open and sudden announcement coming from such a source would simply, as it did, check all business and destroy what little confidence there was in the future of the trade. We believe that the aim of doing what was done in the manner in which it was done was to force a restriction of the output. We have ourselves repeatedly and emphatically given our opinion on the subject, but did not look forward to its realization until the close of navigation. So far as the interests of the New York companies are concerned, we are still convinced that it would have become necessary before a long time, possibly in November. So far as Philadelphia interests are concerned, it would not be necessary or advisable even till the close of navigation. The Reading Company has persistently objected to it, because it had orders on its books for its entire tonnage for weeks to come. As it controls nearly one half of the tonnage, it is, of course, the most important factor; but if confidence is to be undermined by what looks like an attempt at coercion on the part of one company on the other, a large portion of the orders on the books will melt away. We do not believe that there will be any rupture of the harmonious relations between the companies, because very few if any of them can afford to lead the way in such a course; but it does look now as though a restriction of output will have to be agreed upon a little earlier than it would have naturally come. The market could not have taken all the coal mined by full-time work for the whole of the year; and by an earlier reduction of the output, the average returns to the companies for the three coming months may be as good as though they had waited until a plethora of anthracite in the tide-water markets later on had forced them to stop. The principal duty of the managers of the companies will be to promptly arrive at an understanding on this point. It may cause a good deal of inconvenience to some of them.

Business, of course, is at a stand-still, and will be until the trade has learned to appreciate the fact that the many sensational stories afloat are not based on substantial foundation. The many buyers who have been looking for a break so patiently for many months are, of course, on the tip-toe of expectation, and the dispatches of out-of-town purchasers pouring into the offices here countermanding orders indicate their eagerness to benefit by the situation. Nothing but prompt and decisive measures will undeceive them. The majority of the trade is now carrying heavy stocks, and any fall in prices would be a serious matter. We need hardly report that as yet there has been no actual decline.

Bituminous.

Were it not for the fact that the current business is very small, the scarcity of cars in the Clearfield region, and the lack of vessels in shipping ports of Cumberland, coal would tend to improve prices. The incoming steamers are generally light in freight and carry considerable coal for their return voyages, so that the steamer trade is more than usually dull.

STATISTICS OF COAL PRODUCTION.

Belvidere-Delaware Railroad Report for the week ended September 29th:

	Week.	Year. 1883.	Year. 1882.
Coal for shipment at Coal Port (Trenton)	3,235	87,615	67,727
Coal for shipment at South Amboy	9,958	562,447	618,066
Coal for distribution	21,473	608,528	529,746
Coal for company's use	3,746	118,858	95,322
Total	38,412	1,377,448	1,310,861
Increase		66,587	
Decrease			

Horsford's Acid Phosphate

For Wakefulness.

Dr. Wm. P. Clothier, Buffalo, N. Y., says: "I prescribed it for a Catholic priest, who was a hard student, for wakefulness, extreme nervousness, etc. He reports great benefit."

WANTED.—BY A THOROUGHLY COMpetent Map-Draftsman, a connection with a Mining Company, Surveying or Engineering firm—East or West. Especially familiar with mining work. Would also accept a position of trust. Best of references as to capacity and character given. Address, LEO ROSENBERG, 35 Broadway, New York.

WANTED.—A FIRST-CLASS MAN, CAPAble of taking full charge of large Works for the Reduction of Silver and Gold Ores in a Spanish-American country. Must understand the business thoroughly and have the highest references. Address, SILVER ORES care Office Engineering and Mining Journal.

THOSE who have invested capital in the phosphate lands of the Province of Ontario are considerably alarmed at a recent decision in the Quebec courts. The local legislature had passed an act canceling the title to certain crown lands, on the ground that the necessary settler's improvements had not been made, and had sold them as phosphate lands. This act has now been set aside by the courts, and, should their decision be sustained on appeal by higher courts, the titles under which many phosphate mines are worked by American capital would be destroyed.

THE WASTE OF ANTHRACITE COAL.

Mr. CHARLES A. ASHBURNER, geologist in charge of the anthracite district of the Pennsylvania Survey, has recently read before the Engineers' Club of Philadelphia an interesting paper on the estimation of the contents of highly plicated coal-beds, to which Mr. ARTHUR WINSLOW, one of his assistants, has contributed a mathematical discussion of the errors involved in the method employed. Mr. ASHBURNER states this method (which is the one proposed by him two years ago, in a paper before the Institute of Mining Engineers) substantially as follows: The contour-survey of the coal-bed having been made, it is desired to obtain the actual area, that is, the area which would result if the surface were developed or ironed out into a horizontal plane. This area, multiplied by the thickness, would give the cubic contents of the bed. To obtain the bed-area, by a graphic method, vertical cross-sections of the contoured bed are constructed perpendicular to the general direction of the coal-basins, and at equal distances apart. The restored position of the bed is constructed where the coal has been eroded. Each of these individual section-lines is developed into a straight line, which represents the distance, "up hill and down hill," along that section, across the basin from outcrop to outcrop. The development of the section is made on each side of its intersection with a vertical plane, arbitrarily located, but preferably near the axis of the basin. The ends of the developed section-lines are then connected by a broken line, which thus incloses approximately the area sought, namely, the total area, "up hill and down," of the basin, including the regular dips, the overturned dips, and the portions removed by erosion.

We do not need Mr. WINSLOW'S calculations to convince us that this method is sufficiently accurate, where the sections are not too far apart, and great irregularities do not occur between them. Mr. ASHBURNER has settled upon 1600 feet as the distance between his parallel sections; and by a test-survey of the eastern end of the Panther Creek basin, he finds that, by putting the sections 800 feet apart, the developed area obtained was 0·344 per cent less than with 1600 feet interval. From this, he concludes that the probable error by the use of 1600-foot intervals is 0·688 per cent. To this should be added the error due to the method of development, which Mr. WINSLOW discusses for spherical and conical contours and for wedge-shaped troughs. In the latter class, he places the Panther Creek basin, and determines the error at 0·217 per cent (deficiency). Added to the error for sectional intervals, this gives a total error in area of 0·905, or say 1 per cent. Considering that the area thus obtained has to be multiplied by the average thickness of the bed, and allowances have to be made for eroded coal, and for crushed and dirty coal, we are quite ready to say that this one element of a calculation in which the other elements are largelye stimated, is thus determined with almost unnecessary accuracy.

But the question suggests itself, whether this elaborate graphic method is required. Why could not the *horizontal* or cadastral area be simply multiplied into the *vertical* thickness? This eliminates at once the errors which Mr. WINSLOW has discussed with the aid of the calculus; and the sources of error which it substitutes are probably less serious. Indeed, they are present to some extent in Mr. ASHBURNER'S method. For, after he has determined his "developed area," he must still obtain from columnar sections an average thickness by which to multiply it; and it is quite as easy to get the average vertical thickness as the average thickness perpendicular to the roof and floor. In fact, the latter must often, in each single measurement, be determined from the former. In the case of a bed of uniform thickness with frequent changes of dip, it might be easier to ascertain the "developed area," and multiply by the uniform thickness, than to take the cadastral area and try to determine an average vertical thickness from a sufficient number of measurements of a vertical thickness constantly varying with the dip. But such a case scarcely ever arises in practice; for in practice plicated beds vary in thickness anyhow. The only other difficulty in the simpler method we suggest is that, where dips are overturned, this method would take no account of the duplication of the bed within a given area. But as Mr. ASHBURNER, employing a method which laboriously includes these overturned dips, would have to subtract them afterward, because they almost invariably contain crushed and worthless coal, this objection visibly dwindles, if it does not disappear.

We are not certain, however, that this method would be for all cases the most convenient; and we will not quarrel with Mr. ASHBURNER about his preference. His forthcoming volume will doubtless give in detail the calculations of special cases. We shall welcome that volume as a valuable contribution to the literature of the important question of waste in mining anthracite; and meanwhile, we are glad to give, through Mr. ASHBURNER'S courtesy, the figures he has obtained for the property of the Lehigh Coal and Navigation Company, in the Panther Creek Valley, between Mauch Chunk and Tamaqua. By careful work, he arrives at the following result:

	Tons.
1. Amount of coal originally contained in the basin	1,032,997,131
2. Original amount in the exploited area	92,188,922
3. Amount taken out (to January 1st, 1883)	54,115,834
4. Which has produced in marketable fuel	24,817,361
5. Estimated amount still accessible in old workings within the exploited area	10,000,000
6. Which will produce in marketable fuel	3,400,000

The difference between No. 2 and No. 3 represents the amount left underground by wasteful methods of working, and No. 5 may be taken as representing a portion of that loss which better economy and better engineering can still recover. Mr. ASHBURNER has had the advantage of a careful record, kept for two years, of the distribution of every pound of

Digitized by Google

coal which came from the mines; and combining this with the general data above summarized (the details of which for each separate colliery will appear in his volume), he reaches the following conclusions for the mining industry of the Panther Creek Valley:

	Percentage left in mine.	Percentage sent to culm-bank.	Percentage converted into fuel
From 1820 to Jan. 1st, 1883.....	41	32	27
For 2 years, from Jan. 1st, 1881, to Jan. 1st, 1883..	30	24	46

These conclusions differ widely from the statements of some of our best anthracite engineers; and the unusual care with which they have been obtained will attract to them much interest. The improvement indicated by the final figures is highly creditable to the management of the Lehigh Coal and Navigation Company. It indicates great progress, both in the mining and in the preparation of coal—principally, we think, in the latter. That is to say, improved breaker machinery and jigs for washing coal have permitted a good deal of coal to be mined which was formerly left underground as too dirty for preparation, while at the same time, they have permitted the preparation of clean small sizes, formerly thrown away with the dirt, but now esteemed for many purposes a favorite fuel. It would be instructive to learn how much of the diminished waste is due to these causes, and how much to real improvement in underground work. Perhaps Mr. ASHBURNER'S report will tell us something on this head.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

Mr. Alfred R. West and the Guanacevi Mining Company.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Seeing in your issue of September 29th a communication from a Mr. J. J. Downing, in regard to the Guanacevi Mining Company, in which my name is freely used, I would say that my name has been used in a number of the transactions of this company, and always against my consent, having repeatedly forbidden its use in any way. I would like parties connected with this company in any way to write me, and I will give them full information in regard to this company's mines.

Respectfully yours, ALFRED R. WEST.

DENVER, COLO., Oct. 4.

THE TROY MEETING OF THE AMERICAN INSTITUTE OF MINING ENGINEERS.

A large number of members had gathered in Keenan Hall, Troy, on Tuesday evening, when Mr. R. W. Hunt, President of the Institute, called the meeting to order, and introduced the Hon. Martin I. Townsend, who delivered an address of welcome, to which Dr. R. W. Raymond responded.

Professor T. Egleston was then called upon for his paper on

RECENT RESEARCHES ON GOLD.

Professor Egleston has been trying hard to find gold that will not amalgamate, but did not succeed so long as he was working in the wet way. He suspected that arsenic and antimony might be the cause of the losses of gold in working ores on a large scale, and hit upon the happy thought of melting mispickel together with given quantities of metallic gold, as he had no auriferous mispickel ores at his disposal. This fused material he roasted with the greatest care; and when he tried to amalgamate the gold, he could only get from 40 to 50 per cent out of it, although he tried the Designolle process with and without acids. He found the rest of the gold in the tailings. This discovery Professor Egleston believed to be one of importance, and he is now engaged in following out the cue it furnished him. He repeated former experiments, by which he claims to have shown that beaten gold will not amalgamate, at least not before it has been annealed. He obtained gold used for jewelry from Tiffany & Co., of New York City, rolled it down as far as he could, and then hammered it. It would not amalgamate as usual; but, after it had been put into an acid bath or brushed, it would promptly amalgamate. Professor Egleston reached the conclusion that there must be a film on the surface of the gold-dust which prevented it from being attacked by the mercury, and he has now set himself the task of finding out what this film is. It is not grease, because he avoided that with the most scrupulous care; but Professor Egleston suspects arsenic, antimony, lead, zinc, or copper. Professor Egleston did not enlighten the meeting as to the methods by which he proposes to solve this delicate question, but he has promised to follow the matter up. He has been vainly trying to get "rusty" gold, but as yet has not been able to secure any. If there is such a thing, the difficulty in amalgamating it is probably due to deposition of some metal or substance on the outside of the gold.

Mr. R. P. Rothwell, in opening the discussion on Professor Egleston's record of the results of his researches, stated that he had worked hundreds of tons of auriferous mispickel, and had not found it as refractory as it was represented to be in the paper. By amalgamating previously roasted ore, he had obtained from 80 to 86 per cent of the gold; and by chlorination, which requires a much more perfect roast, he had taken out up to 94½ per cent. Professor Egleston believed that the explanation of the discrepancy between these results obtained on a large scale, and the results of his laboratory test, lay in the fact that he had to prepare his auriferous mispickel artificially.

Dr. R. W. Raymond then followed with his paper on the

LAW OF THE APEX.

Dr. Raymond, speaking often in a humorous strain, sketched briefly the historical development of our national mining laws, and then dwelt in particular on the ambiguities growing out of the introduction in the last law of the word "apex." He illustrated how the law had been interpreted in seven different ways, when it referred to wide veins in particular. He gave suggestions as to the means of avoiding much of the hardship of the law, and spoke strongly, in concluding, in favor of square locations, which are now, in consequence of a recent decision of a United States Court in Colorado, on placer claims, practically in force, pending a decision of a higher court.

After a few brief announcements, the meeting adjourned, the members gathering at the Troy Club, where they for the first time experienced that Trojan hospitality which was to contribute so largely toward making the meeting so successful a one.

Among the members attending the meeting are:

R. W. Hunt, President, Troy; Dr. T. W. Drown, Secretary; John Fritz, Bethlehem, Pa.; J. E. Johnson, Longdale, Va.; W. S. De Camp, Boonton, N. J.; W. F. Durfee, Bridgeport, Conn.; P. Barnes, Joliet, Ill.; P. Roberts, Philadelphia; Philip W. Moen, Worcester, Mass.; W. S. Saunders, New York City; Alfred E. Hunt, Pittsburg; Frederick P. Dewey, Washington, D. C.; Stephen Baldwin, New York City; Martin Coryell, Lambertville, N. J.; R. W. Raymond, New York City; John Birkinbine, Philadelphia; I. P. Pardee, Stanhope, N. J.; E. S. Moffat, Scranton, Pa.; A. B. De Saulles, Dunbar, Pa.; R. P. Rothwell, New York City; Dr. Thomas Egleston, New York City; J. C. Platt, Waterford, N. Y.; J. A. Burden, H. Burden, Henry C. Shaw, John H. Mars, J. M. Sherrerd, Troy; J. C. Bayles, A. F. Hill, C. A. Stetefeldt, C. M. Rolker, New York City; Dr. Persifor Frazer, Philadelphia; L. G. Laureau, New York City; Dr. Fr. M. Wolff, Berlin, Germany; W. B. Kunhardt, G. Curtis, New York City; R. Crocker, South Pueblo, Colo.; G. J. Atkins, Pottsville, Pa.; Robert Forsyth, Chicago, Ill.; J. B. Mackintosh, Hoboken, N. J.; Charles Kirchhoff, Jr., New York City.

WEDNESDAY'S PROCEEDINGS.

Early in the morning, the members were driven in carriages to the works of Messrs. Fuller & Warren, of the Clinton Stove Foundry, a very large establishment, a good representative of a very large and flourishing industry, of which the sister cities, Albany and Troy, are the great centers in this country. They witnessed the molding, and went through a number of other shops in which are carried out the many auxiliary processes required to turn out the bright and cheerful stoves for the most luxurious as well as the most humble homes. Many details in the system of organization of so large an establishment were explained to the visitors.

A visit was next made to the merchant steel and rail mills of the Albany & Rensselaer Iron and Steel Company, which we described fully in a recent issue. All the departments were running full, and the works were seen to the best advantage.

Again taking the carriages, the members were driven to the Burden Iron-Works near by, and were at once taken to the most interesting feature of the establishment, the horseshoe mill. The iron is rolled down in a number of two-high trains to the proper section for the horseshoes, and after leaving the rolls, is run into long heating-furnaces entering one end, and as it issues from the other end, it is delivered directly into the horseshoe machines, of which there are in all eight, three of them being in the main mill. These machines, which were designed by the late Mr. Burden, seize the red-hot bars, and by a series of movements which it would be impossible to describe without the aid of drawings, cut it into lengths, and bend it into the form of the horseshoe, simultaneously giving it the two cuts under the shoe in which are located the holes through which the nails pass. Thus prepared, the blanks drop upon an underground carrier, which takes them to an adjoining building, in which stands a long row of punches, by the aid of which the holes are punched through the blank. As yet, the latter are of uniform width. They are delivered into heating-furnaces in which they are brought to a red-heat. They are then drawn out, and by boys are fed into the swaging-machines, the invention of Mr. James C. Burden. These machines, of which there are six, give the shoe its final form. The works have a capacity of 160 tons of horseshoes per day. After admiring the shipping facilities of the horseshoe department, the visitors were taken through the puddling and merchant mills, in which the well-known brand of iron, "Burden's Best," is manufactured. The mills are very extensive, have modern furnaces, two-high rolls and vertical engines throughout. After a walk through the extensive machine-shops, a visit was paid to the blast-furnaces, one of which was just preparing to go into blast. Blast is furnished by two horizontal engines designed by the late Mr. Rumpf, of the West Point Foundry. After being shown the beautifully equipped general offices of the works, the members were taken to the "water-mill," the chief curiosity of which is a 60-foot water-wheel, built in 1850, which has since been running steadily, needing only occasional trifling repairs of the wood-work. This wheel was designed by the late Mr. Burden, the stamp of whose genius the works still bear in many departments.

After partaking of the hospitality of Mr. Burden, at his country-seat, the members resumed work, and went to the Albany mill of the Albany & Rensselaer Iron and Steel Company, and later to the Bessemer mill.

THE SECOND SESSION

was opened by a paper read by Mr. Robert Forsyth, of Chicago, on the

BESSEMER PLANT OF THE NORTH CHICAGO ROLLING-MILL COMPANY,

which was designed at a time when the adoption of the basic process in this country seemed imminent, and it was therefore thought best to so arrange the new plant at South Chicago as to allow for its introduction; and in view of the economy of fuel and labor, it was decided to build a plant permitting at the same time the use of metal directly from the blast-furnace. The small size of the ingots, 12 inches square and long enough for three and four rails, and the large number cast from each heat of 10 tons made it necessary to provide a good deal of room in the casting-pit and to furnish extra facilities for handling ingots. To meet the delays incident to the basic process, it was decided that three vessels should be used with the Holley removable converter-shell, a plan involving the conveyance of the old vessel shell to a convenient repair-shop and the substitution of a newly lined shell in its place. The difficulty of working these vessels to one casting-pit without the use of cumbersome and unwieldy ladle cranes was obvi-

Digitized by Google

ated by the method suggested by Mr. L. G. Laureau, of transferring the steel ladle from the receiving-cranes to the casting-crane. Between the jibs of the cranes was put, at South Chicago, a short piece of fixed track on which the ladle may rest on its transit from crane to crane. The use of the transfer ladle permits the iron and spiegel ladles to be brought in front of the vessels instead of behind them, thus allowing the use of simple runners or none at all.

The buildings are: A boiler-house, 118 feet by 44 feet; an engine-house, 114 by 48 feet; a converting building, 108½ feet by 102½ feet, to which adjoin a spiegel cupola building, 66 feet by 47 feet, and a shed; a repair shop, 238 feet by 75, with a ladle drying shed; a producer-house, 60 by 44 feet; and a grinding-house, 100 by 50 feet; the total ground area covered by the work being about 60,000 square feet.

The engine-house contains two separate horizontal condensing blowing-engines, with steam-cylinders 54 inches in diameter, and air-cylinders 66 inches in diameter, by 60 inches stroke, the design being by Mr. Kriete, the chief-engineer of the company.

The converting building contains three 10-ton vessels, two receiving ladle cranes, one casting ladle crane, three ingot cranes and one crane used in cleaning and handling ladles. The ingot and ladle cranes are placed symmetrically about a casting-pit of 20-feet radius, and command its whole circumference. In this pit, there is room for forty 12-inch molds, occupying nearly three quarters of the available casting space, and there is an ingot crane for each set of molds, so that three heats may be working at the same time, if necessary.

The three 10-ton vessels stand with their trunnion axes in the same line, 18 feet above general level and are 26 feet apart from center to center. Each vessel, which is of the old form, not being concentric, has a cast-iron trunnion section in one piece, inside of which is hung the shell. The vessels are rotated by horizontal hydraulic cylinders, 20 inches in diameter, with racks and pinions of cast-iron. They turn through an arc of 270 degrees. Under each vessel, is placed an hydraulic lift for handling the vessel shell, and putting on bottoms, with a 24-inch plunger and 8-foot stroke. Though not used, one of these lifts was found to have a capacity of 98,000 pounds at 300 pounds accumulator pressure.

In front of the vessels, and 19 feet above general level, runs the elevated railroad, on which metal and spiegel are brought, the one from the blast-furnace, the other from the spiegel cupola building. The scales and tracks in this building are so arranged that, if necessary, any cupola may be melting siliceous pig.

The metal is brought from the furnace, a distance of 1500 feet, in 10-ton ladles mounted on cars up an incline with an average rise of two feet per 100 to a level siding just outside the converting building. From this siding, carried on arches, the ladle-car is pulled by a special locomotive into the building, and the metal is poured into a short runner directly in front of the vessel.

In front of the vessels, are the two receiving ladle cranes, so placed that both of them may serve the center vessel of the three, while the end vessels are reached by one crane each. The ladle on one of the receiving cranes, when filled with steel, is swung around until it points to the center of the casting-pit, when it is lowered until the outer ends of the jibs rest solid upon iron blocks which carry one end of a piece of fixed track some 10 feet long, placed in line with the crane jibs. The other end of this track is carried upon similar blocks, upon which the jibs of the casting-crane rest when lowered in the same way. The carriage and ladle are thus transferred to the casting-crane.

By the general arrangement of the cranes, the great blowing capacity of the vessels is fully utilized, and the quantity of product becomes a question of keeping the pit clear of ingots.

So far as possible, all work of repair and renewal is taken out of the converting room and done in the repair-shop. Newly lined ladles are dried under a gas firing-hood, of which there are twelve. The bottoms are of the "dish" pattern, and each bottom stands on a car which it never leaves except to go on a vessel. The vessels and bottoms were designed for making heavy charges of direct metal, and having in view the occurrence of "long blows," care was taken to provide plenty of wind. There are 18 tuyeres in the bottom. The blast-pipe on the vessel is 12 inches in diameter, and the blast-main is a 15-inch pipe.

The largest blow on record at South Chicago lasted 45 minutes; but 10 tons of metal with 2 per cent of silicon are commonly blown in from 10 to 12 minutes, and one blow of 9000 pounds was finished in three minutes. At the rate of 12 minutes to a blow, 5 heats an hour can be made regularly; for with three vessels, blowing can go on continually, and by the use of two ladles and ten transfer cranes, a ladle is always ready for a charge when finished. As this rate of working will keep the vessels constantly employed, the possible limit to the product of a Bessemer pit, 600 tons in 12 hours is reached.

The possible need of cupolas for remelting the Sunday iron and using up scrap was recognized in the design, but was not put up. It would seem that, for a plant to work mixed cupola and direct metal, and having a large furnace capacity, the cupolas might be advantageously placed near the furnaces, and be considered, in fact, adjuncts to them, if the office of the cupola is merely to remelt Sunday iron.

The South Chicago practice differs in some points from that at other works. With reasonably good ores, success in working direct depends primarily upon intelligent and scientific furnace management, and in almost equal degree, upon careful and constant watchfulness in the Bessemer works. With the object of knowing what sort of metal is about to be blown, the plan was adopted, at South Chicago, of taking a test from the metal as it ran to the vessel, which was cast in a chill, and cooled at once in water. The fracture of this "chill" enables the blower to judge very accurately of the probable heat of the charge, and the necessary additions to be made. Though the quick determination of the silicon has been brought to great perfection at the Edgar Thomson Works, the chill furnishes all the necessary information in a better form.

It is surprising what great variety of metal the Bessemer process can deal with under favorable circumstances. White iron with 0·75 silicon has been successfully converted, and so has iron with 4 per cent, with all the intermediary grades. But the best metal for direct working is found to be that with from 1 to 1·5 per cent of silicon, partly gray, and with not more than 1 per cent of manganese. Ten tons of such metal can be blown in from 10 to 12 minutes, and, phosphorus being low, will make good steel. The higher limit of silicon is perhaps the safest as affording reasonable security against sulphur, and there is no difficulty in dealing with 2·50 or even 3 per cent of silicon, quantities which insure that sulphur in hurtful amount will not be present.

It became evident, very soon after work began at South Chicago, that there would be difficulty in keeping down the heat of the metal by means of scrap alone, and steam connections were therefore put in to each of the vessel blast-pipes with the object of cooling the metal by means of steam. To Mr. W. R. Walker, is due the credit of having made the use of steam in the Bessmer process a success on a large scale, for all previous applications had been hardly more than experimental. As used at South Chicago, the apparatus consists of a 2-inch pipe tapped into the blast-pipe leading to each vessel. As soon as the metal in blowing shows signs of undue heat, steam is turned on and kept on until, in the judgment of the blower, the proper cooling effect is produced. An enormous quantity of steam is sometimes required, the full opening of a 2-inch pipe at 50 pounds pressure being occasionally given. Nothing can be more effectual than this way of cooling metal. There is no handling of scrap, and the whole matter is under the complete control of the blower, who, by opening a valve, can regulate the temperature of the metal with the greatest nicety. A capital advantage of steam is, that with its aid metal high in silicon can be converted without difficulty, so that a furnace may make pig in which sulphur may be kept low without complaint from the Bessemer works. No removal of sulphur or phosphorus is effected by the use of steam. The steam is evidently condensed before reaching the metal, because the tuyere-box and blast-pipe are quite cold, whereas without steam these parts are usually hot enough to burn the hand, and water runs freely from any leaky joint about the bottom. By using steam, the consumption of scrap may be confined to what the Bessemer works itself produces.

At South Chicago, vessel linings are balled up with finely ground patching stuff, and last for months; and bottoms are made in much the same way. A 10-ton vessel has been lined up in seven hours, and a bottom has made as many as 29 heats, yielding 238 tons of ingots; and the average life of a whole month has been 18¼ heats, yielding 159 tons of ingots, as against 55 at North Chicago in 1875. One hinderance to large output which was foreseen and, so far as possible provided for is the large number of small ingots cast. Thus, to get 381 tons, no less than 436 ingots had to be handled in an equal number of molds. The cranes and trucks are so arranged that this large amount of handling is done without difficulty and without interfering with any other operations. But some mechanical device is very much needed for handling ingots and molds.

President Hunt, in opening the discussion, referred to the introduction of the basic process, stating that an engineer who had closely studied it abroad had come to the conclusion that it would not be profitable to replace the acid by the basic process in this country, unless the difference between Bessemer pig and phosphoric iron was at least $3 per ton. Mr. Durfee called attention to a table giving the results of early experiments on the back pressure in turning converters, and exhibited a design to take the place of the rack movement now generally used to tip converters. Mr. Hunt called attention to the fact that it was Mr. Durfee who had been the first to make a successful blow of Bessemer steel at the experimental works at Wyandotte, the metal being taken directly from a small charcoal blast-furnace. After a few brief remarks by Mr. Durfee and Mr. Forsyth, Mr. Alfred E. Hunt, of Pittsburg, Pa., read his paper:

SOME NOTES AND TESTS OF AN OPEN-HEARTH STEEL CHARGE MADE FOR BOILER-PLATE.

The charge to be described was made in a seven-ton furnace, with a hearth twelve feet long and eight feet wide, with three gas and three air-ports on each side. The stock of the entire heat was charged cold in one hour and five minutes, a part of the pig being first placed upon the bottom to protect it, then upon it the plate-scrap and blooms, and finally the remainder of the pig—some two thousand pounds. In five hours and twenty-five minutes after beginning the charge, the metal was melted down level, and two hundred pounds of hot twelve per cent spiegel were charged, care being taken to have it entirely immersed in the bath. In two hours more, the bath was thoroughly melted and hot, and began to boil; that is, the carbon began to be oxidized and evolved through the bath of covering slag as carbonic acid and carbonic oxide gases. Seventy-five pounds of lumps of Republic specular iron ore were added at this time, increasing the action, so that in ten minutes after, the metal was in active ebullition. A test of the metal showed it to have about 0·90 per cent carbon. One hour after the first ore was added, a test was again taken, after thorough rabbling of the metal, and it was found to be 0·37 per cent carbon. One hundred pounds more of lump Republic ore and about seventy-five pounds of limestone were then added, and fifty minutes later, after the bath was thoroughly rabbled, a test showed the metal to have 0·23 per cent carbon. Twenty-five pounds more of Republic iron ore were added, and the metal allowed to boil for twenty minutes, when a test, after rabbling, showed the carbon to be 0·18 per cent and the manganese to be 0·01 per cent; the slag fracture was vitreous and of a very dark-green color. About forty pounds of limestone were added, and, the metal being hot and in a state of quiet ebullition, a hickory pole of twelve feet length and about four inches diameter, was run through the aperture in the center door and held in a steady inclined position in the bath, with the end touching the bottom, the pole being shoved in farther as it was burned away. The bath was carefully watched to see that the action that ensued was not too violent, the pole being several times pulled out to check the splashing of the metal. This "poling" of the metal lasted for about ten minutes. Ten minutes were then allowed for the bath to quiet down, when, after rabbling, two tests taken in different places in the furnace showed between 0·14 per cent and 0·15 per cent in carbon. The metal was hot, and rapidly cut off a hook of inch iron in the bath, leaving no steel but only slag caught on the hook, on cooling the sharp pointed end that was withdrawn from the furnace. The furnace test of 1½ by 1 by 5 inches long showed a good clear silvery fracture, which had to be indented by a chisel for about three eighths of an inch on each side before giving way to the blows of a heavy sledge. The final addition of 150 pounds of seventy-two per cent ferro-manganese was then added, the metal was thoroughly rabbled and tapped into the ladle just twenty-five minutes after the pole was taken out of the bath, and nine hours and

Digitized by Google

twenty minutes after the first piece of stock was charged. The metal was cast into a hot ladle, and was bottom-poured into four plate ingots 7 inches thick by 37 inches wide by 48 inches long, and weighing about 3300 pounds each; and one ingot, 18 inches square and 48 inches long, on the same group, weighing about 4000 pounds; and one ingot, 7 by 15 by 22 inches, weighing 630 pounds; and one 12-inch square ingot, weighing 1620 pounds, which was top cast. The charge yielded 19,430 pounds of sound ingots, or 92·35 per cent of the charge; 600 pounds of runners and scrap, or 2·85 per cent of the charge; and 1010 pounds loss, or 4·80 per cent of the charge. Two hundred pounds of Republic ore were used in reducing the bath, and 115 pounds of limestone to clear the slag of metal.

The charge consisted of—

No. 1 charcoal Titan pig-iron	6,080	pounds.
Open-hearth plate scrap	4,570	"
Chateaugay blooms (62 in number)	10,100	"
12 per cent German A U spiegel	200	"
Weight of original bath	20,890	"
Final addition of 72 per cent ferro-manganese	150	"
Total charge	21,040	"

The analysis of the finished metal and of the constituents of the charge is as follows:

	Carbon.	Manganese.	Silicon.	Sulphur.	Phosphorus.	Copper.	Silica.	Carbonate of lime.	Iron.

Tests were made, which, though too few to generalize upon, are all typical results which have been confirmed very many times, so that from them, as illustrations merely, the following propositions are stated:

I. There is about 25 per cent reduction in the percentage of elongation in the results of a specimen of soft steel of 8 inches between shoulders from those of two inches in length, and the percentage of elongation varies proportionately to the length of the specimens measured; hence figures, as often given, of the percentage of elongation, without stating the length of the specimens, are meaningless.

II. The percentage of elongation measured at "the moment of failure," gives from 15 per cent to 20 per cent lower results than those measured in the usual way, after the rupture, or as finally automatically recorded by the testing machine.

III. As steel is usually rolled with the most of the work in the direction of the length of the plate, specimens cut transversely to the grain of the metal in such cases give slightly lower results than those cut with the grain.

IV. Soft plate steel, of over one half inch thickness, needs to be reduced from an ingot of at least nine inches thickness. A very important and often occurring cause of defective steel is, that it has not had work enough; that is, has not had sufficient reduction from the ingot to the finished steel.

V. An increase of from two to four thousand pounds per square inch, and a correspondingly lower elongation of from one to three per cent in two-inch length sections of soft plate steel, is obtained by casting ingots twelve inches by sixteen inches in section, and hammering them to slabs of about five inches thickness, and then, after reheating, rolling these slabs into plate steel over plates of the same heat of steel, which are rolled directly from the ingot to the plate, or over ingots rolled to slabs and reheated and re-rolled to plate, showing that there is a sort of hammer-hardening in this soft steel, which the subsequent reheating and rolling do not entirely remove.

VI. Soft steel, of no matter how low carbon, can be hardened to a certain extent by being heated red-hot and plunged into water, and hardened more when plunged into brine, and less when quenched, in oil.

VII. Soft steel, of no matter how low carbon, can be hardened, and then the temper drawn to a certain extent, as can be easily proved by the testing-machine.

VIII. If soft steel plates are finished at the rolls too cold, or are too suddenly chilled in the cooling down, a considerable decrease in ductility and increase in tenacity will be obtained between specimens from the plate without further treatment and specimens which have been carefully annealed before dressing.

IX. For soft plate steel bottom-poured ingots are more solid and uniform in structure, and yield much better plates than top-poured ingots.

X. The percentage of carbon in steel for practical work is usually obtained by the color method. It is doubtful whether there are a half-dozen laboratories in the country where the color standards would perfectly agree; so that before a general intelligent discussion of the properties of various kinds of steel can be had, it will be necessary for the steel-works chemists to agree more exactly as to their color standards for carbon determinations.

A few remarks bearing on the subject were made by Mr. P. Barnes, and, in the absence of further discussion, the Secretary read a paper by Mr. G. C. Stone, of Newark, N. J., on

THE DETERMINATION OF MANGANESE IN SPIEGEL,

in which were submitted the results obtained by analyzing the same sample of spiegel by different methods.

In all, forty-six determinations by fifteen chemists using ten methods are given; these methods may be divided into four classes, that is, 1st. Williams's method. 2d. Other volumetric methods. 3d. Methods in which the manganese is precipitated and weighed as phosphate. 4th. Methods in which the manganese is precipitated as basic carbonate or hydrate in presence of large quantities of alkaline salts and weighed as Mn_3O_4. The results may be divided into, 1st, those below 13 per cent; 2d, those between 13 and 14 per cent; and, 3d, those above 14 per cent. If they are so divided, it will be seen that 71 per cent of the results below 13 per cent were by methods of the 1st class, 87 per cent of those between 13 and 14 per cent were by methods of the 2d and 3d classes, and 83 per cent of those above 14 per cent were by the 4th class.

Mr. Mackintosh, of Hoboken, submitted the data given in the paper to a mathematical analysis, while Mr. Alfred E. Hunt spoke of the homogeneity of samples of spiegel, referring to the fact that the finer material is richer in manganese than the coarser stuff.

ASBESTOS AND ITS APPLICATIONS.

Asbestos, a peculiar variety of the amphibole or hornblende family of minerals, is most largely found in Canada and Italy. It occurs in regular layers or veins, generally as a grayish-green rock made up of innumerable fine crystalline fibers which become soft, white, and of a silky luster when separated from each other by slight pressure. The thickness of the veins varies considerably in different localities, from a thin sheet, in the case of the variety known as mountain leather, to several inches in the deposits of the delicate amianthus found in the older crystalline rocks, in the Pyrenees, the Alps of Dauphiny, the St. Gothard, the Savoy, and Corsica. A single fiber of asbestos, heated in the flame of a blow-pipe, readily fuses to a white enamel, the varieties containing most iron being most easily fused, but in the mass it resists the heat of an ordinary flame, and for this reason it has recently begun to attract considerable attention. Unfortunately, the fibers of asbestos differ from all other known fibers in having a perfectly smooth surface and in being much less elastic than those of either animal or vegetable origin, in consequence of which all efforts to spin and weave them by modern machinery have until very recently entirely failed. In addition to amianthus and mountain leather, there are several other varieties of asbestos, for instance, mountain cork, which is a brownish or dirty-white deposit, less flexible and less regular than amianthus and mountain leather, and so light as to float on water; mountain wood, a soft, opaque, brownish colored variety, which melts to a black slag before the blow-pipe; and lastly, the common asbestos, which has recently been discovered in large quantities in Canada, in veins from one inch to two inches thick, and which is the kind most generally used for manufacturing the various articles to which we shall have occasion to refer.

The introduction of asbestos for such purposes as engine packing and jointing for pipes has been attended with very considerable difficulty. Of all materials, it is perhaps that which requires the most careful manufacture and intelligence in adapting it to its special purposes; and when these have not been sufficiently exercised, users have been disappointed, and have not unfrequently given up the trial in disgust. As already stated, the peculiarity incidental to asbestos fiber for a long time baffled all attempts to spin it into a yarn without the intermixture of a certain proportion of flax or other vegetable fiber. Within the last few years, however, the difficulty has been overcome, and yarns capable of withstanding great tensile stresses can now be readily produced by machinery specially constructed for the purpose. One of the most important applications of this yarn is for the manufacture of steam packings. In making packing, it was at first not sufficiently recognized that the fibers of asbestos were apt to be largely charged with minute particles of pyrites; and until this fact was appreciated, it was often found that the piston-rods were scored, the damage being attributed to the action of the asbestos itself, instead of to the impurities it contained. To obviate this defect, it therefore became necessary to thoroughly cleanse the asbestos from all stone and grit before spinning, for which duty machinery had to be adapted. The yarn now produced is quite pure, and is capable of being woven into almost any kind of fabric. But it was soon ascertained that special cases required special treatment, and though the plaited packing was generally satisfactory, it became evident that something else was wanted in the case of steam-engines with extremely high piston speeds. To meet this demand, the yarn was first woven into a cloth, which, being slightly water-proofed with vulcanized India rubber, was rolled up into a rope in much the same way as the canvas is treated in what is known as Tuck's packing, only without the rubber core. This packing answered admirably, and is much used in cases where the rapid destruction of ordinary packings gave rise to most serious inconvenience. The enduring powers of this asbestos block packing are quite remarkable. In one place, on being taken out after twelve months' working with steam of 70 pounds pressure, it was found to be perfectly good, and was accordingly replaced. It has often been erroneously stated that asbestos packing could be used without lubrication. No greater mistake could exist. It not only requires a good supply of oil, but demands careful attention on the part of the engineer in charge. If carefully manufactured and properly used, asbestos is the best material for packing the glands of steam-engines; but if ignorantly made up and carelessly used, it is probably the worst.

A great deal of yarn is woven into cloth, and is adopted for a great variety of purposes. One noteworthy application is for fire-proof curtains, and several of these have been supplied by Mr. Bell for theaters in Great Britain, the United States, and elsewhere. So important is this material considered in regard to the prevention of the spread of conflagrations that a company has been formed in New York with the sole object of extending its use in the shape of protective shields, either permanently fixed or applied in case of a sudden emergency. In relation to this application, a fire-shield was recently exhibited at a meeting of the Firemen's Convention held at Rochester, N. Y., and attracted very great attention. The shield consisted of a piece of pure asbestos cloth about twenty feet square, and supported on an iron frame. A pile of pine wood saturated with petroleum and tar was built on the windward side

Digitized by Google

of the curtain, and set on fire. The blaze was tremendous, and the heat so intense that persons could not stand within fifty feet of the burning mass on the exposed side. On the side protected by the shield, however, the heat was scarcely felt, and a dummy erection of wood and glass, which was placed close beside it, was not in any way injured. The curtain, of course, did not suffer, and was as good after the experiment as it was before.

For forming the joints of pipes exposed to the action of moisture, and for man and mud-hole doors requiring frequent removal, asbestos woven cloth is very largely in demand. In these cases, asbestos millboard, which is the cheapest form of jointing material, is comparatively worthless, if, indeed, it is not absolutely objectionable, from its permeability to water, which soaks through and attacks the iron of the bolts, and it was therefore necessary to devise a combination which would effectually resist the heat and damp. This is provided in what is known as asbestos and India-rubber woven sheeting, which is made in any thickness, and is supplied either in sheets to cut to the required shape, or in a tape from one to two inches wide, which can be cut to lengths and bent to circle or oval without puckering. When all other materials have failed to give satisfaction, this has answered admirably, and in the case of man-hole and mud-hole doors and feed-water pipes, the joint can be broken twenty times without requiring renewal of the strip.

The last application of the yarn which we shall mention is the manufacture of rope and cord. Having great tensile strength, and being unaffected by heat and damp, this material is in course of introduction for sash-lines and for ropes of fire-escapes. It is also adopted for covering rollers in print-works, especially when aniline dyes are used, and in cases when it it exposed to great heat and to the action of hydrochloric acid. Asbestos cord has also been found to be the most effectual material for making the joints of the hot-air pipes for blast-furnaces, which are exposed to an exceedingly high temperature. The jointing consists of an iron ring wrapped with the cord, which is simply put in place and nipped between two flanges, and, being unaffected by heat, lasts a very long time.

We now come to an entirely different manufacture of asbestos, in which the rock, after being broken down and reduced to fluff, is pulped and formed by pressure into sheets from $\frac{1}{16}$ inch to $\frac{1}{4}$ inch in thickness. This millboard, as it is called, is used for making joints not exposed to the action of moisture, such as for dry steam, air, and gas. When properly made and used with faced surfaces, this material affords the easiest and most cleanly method of making a joint, while, if the faces are previously painted over with boiled oil, the danger of having a troublesome leaky joint is reduced to a minimum. The board is easily cut to the desired size, and as no time is required for drying and setting, steam can be turned on as soon as the bolts are screwed up. A much commoner and cheaper description, though it still possesses most of the essential qualities, is manufactured for fire-proofing floors and ceilings. It is made in sheets about $\frac{1}{32}$ inch thick, and is applied in the simplest possible way, either above or below the joists. It is also used for lining the walls of wooden buildings, where, from its non-conducting and fire-proof qualities, it affords an immense protection in case of the outbreak of fire. As an insulator of electricity, asbestos in one form or another is greatly sought after. Millboard has for some time been used in the construction of dynamos, while cables and leads covered with plaited yarn have been adopted in many installations. The remaining uses of asbestos which we have to notice appear to be mainly in the production of fire-proof cement and putty, for which there is considerable demand for certain kinds of joints, and in the manufacture of fire and acid-proof lumps, blocks, and bricks. The ordinary gas fire is familiar to every one, and it will suffice to point out that asbestos enters largely into the composition of the artificial fuel upon which the success of the fire in a great measure depends.

THE PRESENT CONDITION OF THE MINES OF THE TOMBSTONE MILL AND MINING COMPANY.

The tendency of Eastern purchasers to secure a large amount of territory when they are buying mines has often been laughed at by their Western rivals, who know that, if one mine is a failure, the fortunes of the owners will not be improved by the possession of other territory of no better quality. But this reasoning must contain a fallacy; for there is more than one instance in the recent mining history of the West of marked advantages springing from this habit of Eastern investors. The Tombstone Mill and Mining Company is one of the best examples of this system of purchase. Holding nearly a dozen mining claims, the company has made four of them into extensive mines, and has carried work to a point of useful production on one more with the prospect of still further extensions. Their producing mines are the Good Enough, Tough Nut, West Side, and Lucky Cuss, and the Defense has also been yielding steadily, though without being pushed. Among their other claims is the Tribute, a claim which has always borne the reputation of containing a good vein, though until two months ago no one had found it. At that time, some prospectors out of work found croppings, and secured from the company a short lease. The vein is parallel with the West Side claim and immediately adjoining it. Its ore has a close resemblance to that from the latter mine, and the officers of the company say it will be opened by them as soon as the lease expires. Nearly parallel with this vein and on the other side of the West Side, is the Defense, a claim that contains a vein of base ore, not suitable for free milling. This has been worked steadily for a year by a small force, the product being a smelting ore, which has been sent to the company's furnace. Besides these openings, some ore has been taken from the Intervenor, East Side, Old Guard, and other claims, all in the same portion of the Tombstone District, and lying between the old belt of free-milling ores and the newly opened manganese mines.

A new strike was also made on the Tough Nut mine of the Tombstone Company, and ore found extending from the surface down to the depth of about 90 feet. Its position is directly among the large ore-bodies which have made this company so prominent; but whether it will end in an addition to them or continue without increasing its dimensions, can not be predicted. The high grade of the ore is considered a favorable indication in Tombstone, whether this high grade belongs to a surface outcrop or an underground body.

But though the other claims have yielded a considerable amount of ore, the Tombstone Company's work has been done mainly in the West Side mine, where three important tasks have been accomplished recently, or undertaken—stoping out the 3d level, opening the 4th level, and sinking to the 5th level. The last-mentioned is the completed work. The 5th level was reached in September, and a cross-cut run to the vein before the close of the month.

The 4th level was begun the last of May, and is now nearly four hundred feet long. It has shown a greater length of ore-bearing ground than any other level opened in the mine. At present, it extends from a point about 180 feet north of No. 3 shaft to a point more than 200 feet south of it, and ore has been found at two other points, which carry the line of prospecting 400 feet farther south. The winzes necessary for the air-connections in this direction are already sunk, and the opening of the drift will be greatly facilitated.

The opening of this mine has developed two interesting points. The west side claim is 1500 feet long, and the vein-croppings are very plain from the north end line to No. 1 shaft, a distance of about 1100 feet. The vein is just what the croppings indicate it to be, a nearly straight line of ore, not remarkably thick, but more than usually continuous. Near the surface, the vein was mostly from two to four feet thick, and remarkably straight. On the third level, undulations in the course came in, and at one point, the vein branched. One of these branches continues to bear the name *main* vein, because it preserves the old direction, while the other trends to the east.

Between these two branches lay a body of ore of unusual formation. Instead of being a solid mass, with barren spots distributed irregularly, it was made up of ore-seams lying between beds of barren limestone. The ore-seams ran from one of the vein branches to the other, lying directly across the regular direction of the vein. In form, the mass viewed from the south had the shape of a pear; but a side view showed that its length was much greater than its width, being 110 feet long and 40 at the greatest width. Added to the peculiarities of this singular formation was the fact that the alternate layers of ore and limestone were strongly bent, dipping 50 degrees north at the north end, and about 55 degrees south at the south end. The ore was of high grade, and always richest at the apex of the fold.

Connected with this body and forming one of its downward prolongations, were "shoots" or layers of ore, that have been encountered again on the fourth level. In one of them, was found a mass of telluride ore, from which several tons of ore, worth $1200 per ton, were sent to the mill. This development is unique in the Tombstone District, though tellurides in small pin-points have been seen in the ores before.

The other point demonstrated by the opening of the mine is the steady improvement of the south end as depth is reached. At this place, there is a wide ravine on the surface, about fifty feet deep. Under this ravine, the vein was so poor on the first level that the drift was not carried across it. On the second level, the ravine was crossed in ore that was just below milling value. Improvement continued to the 3d level, where the stopes are somewhat extensive, and some bunches of excellent ore have been found. In this portion of the mine, there is a winze down to the 4th level, which gave an excellent grade of ore through its whole depth.

These conditions, probably, point to the effect of surface action in dissolving and redistributing the contents of the vein; and if this is the case, the south end of the West Side may become for a time its richest ground, carrying in one level the accumulated reserves of two or three hundred feet of leached-out ground.

The West Side ore contains more gold than the ore from the flat ore-bodies which this company has worked, and also an amount of lead, which indicates that the concentrating-works of the company will have a successful run.

Of the other mines of the company, the Lucky Cuss is the only one that has exhibited any peculiarities of interest. There the manganese used in the lead furnace as flux is mined, and also some lead ore containing silver. A new outcrop of the latter character was found during the summer, and has yielded good ore.

In mining the manganese, small pockets of carbonate ore, rich both in lead and silver, have always been encountered; and at the depth of 175 feet, there has been a more extensive change in the composition of the vein-matter. The ore contains less manganese and more iron, alumina, lead, and silver than before. A change of this kind was expected, but it had been delayed so long that its probability had become doubtful, especially as other manganese mines in the neighborhood had been worked much deeper and more extensively than the Lucky Cuss without finding any but transient changes in the constitution of the vein-matter, or any but insignificant bodies of carbonate ore.

It is quite possible that the Lucky Cuss may return to the strict manganiferous ore with which it began. In one respect, however, it is not likely to go back on its record. Its manganese has improved materially in silver value as the mine deepened, and this is reported to be the case in other Tombstone mines of like character, so that mines with a manganese gangue may be put down among the class that lose their metal by exposure to the elements.

The works for treating the company's ore are situated at Charleston, ten miles from Tombstone. There is an amalgamating mill for the "dry" silver ores, a concentrating establishment for the tailings and ores that contain lead, and a furnace where the concentrates are smelted.

The company has been obliged to renovate the silver mill almost completely, new pans having been put in throughout during the summer. Practically, this makes a new mill of it, with just as good prospect of running four years to another repairing time as it ever had.

Besides this, the old concentrating machines have been removed to a new building, where they will work with new machines that will more than double the capacity of the works. The new works are nearly finished, and will probably be running before November. They have been so planned that the entire daily product of the mill will be treated in addition to a quantity of old tailings as great as was treated in the first concentrating-works, and arrangements have also been provided for crushing and concentrating ores that are too base to be proper subjects for treatment by amalgamation. These arrangements secure the provision of sufficient material to keep the furnace constantly at work,

Digitized by Google

and in fact may require the increase of the company's smelting plant. In addition to these arrangements, a long lease of a lead mine has been secured, the ore from which has been used in August and September.

The policy which has controlled all these arrangements was based upon the evidence, shown in the last report of the superintendent, that the tailing-beds resulting from the treatment of the company's ores, taken in connection with the Lucky Cuss mine, contained silver enough to insure the payment of the company's obligations, without drawing upon the new supplies of the mines. The object sought was to organize the treatment of these tailings as an entirely separate branch of the company's business, independent of future contingencies; so that the whole system, once set in operation, would finally result in the payment of all obligations. This has now been done, and it is believed that the only questions that remain to be considered are those that relate to increasing the rapidity of this work and lessening the time of realization. Some experience has been had in this respect, and steps taken, which, however, can not be completed until November. The furnace has run steadily and successfully since last May, the only difficulties encountered being in matters of detail which were corrected as they developed themselves.

Taken as a whole, the system of work and the plant provided at Charleston form, probably, the most complete establishment in the country for the treatment of dry silver ores. While the new concentrating-works were in progress, the company bought considerable quantities of ores from Tombstone mines, smelting them with the accumulation of concentrates from its machines. The result showed that, even in this camp of "dry" silver ores, there is quite a production of ore suitable for furnace treatment.

The introduction of concentrators and a furnace as a mode of treating tailings from a silver mill is undoubtedly an interesting innovation on the usual practice. Its results have been favorable. The tailing-beds have already yielded a greater profit than could have been looked for from any other mode of treatment. The fact that the whole work has been of an experimental character until now prevents an accurate comparison of results. The purchase of ores to fill out the interregnum caused by rebuilding the concentration-works would naturally lessen profits, besides disturbing the regular operation of the system; but the company is reported to have derived a steady profit from its operations, and to have paid a large sum on its indebtedness.

THE SOURCES OF LOSS IN THE COMBUSTION OF FUEL.

The many tests made on the continent during the past fifteen or twenty years have not furnished much material of value for ascertaining the comparative efficiency of boiler-furnaces, and the combustion of fuel in them. As Mr. William Kent pointed out recently, the few data on record here can not be accepted, although some of them appear to us to possess a value as giving data as to the relative merit of different kinds of fuel. The Germans, in their thorough way of taking up technical subjects, have quite recently struggled with this one, and two leading associations, the Society of Engineers and the Association of Steam-Boiler Users, appointed a committee which has just reported. Mere competitive tests, without a full examination of the entire process of combustion, are of little use. The work of the fireman must be checked by chemical analyses and a complete set of observations. There are cases on record where the same fireman, using the same coal in the same boiler on two successive days, evaporated 8·45 and 7·37 pounds of water per pound of fuel. The Germans, therefore, insist that the only means of getting at a good estimate of the work of a fire-place is to analyze the gases of combustion, and compare the loss of heat through that source with the theoretical calorific value of the fuel. They would thus be saved the expense of many costly experiments to test boiler appliances and settings, for which their inventors generally claim, in a modest way, a saving of at least from 20 to 30 per cent of fuel. It is true that such an examination of the gases entails expenditure and is troublesome; but the results afford a clew to many sources of loss, and thus pave the way for an improvement.

The report of the committee referred to gives interesting instructions on the method of computing the theoretical calorific value of a fuel and the loss through the escaping gases of combustion.

The quantity of air L required for the complete combustion of a kilogram of fuel, containing by analysis c parts of carbon, h parts of hydrogen, s parts of sulphur, o parts of oxygen, and w parts of water, may be calculated as follows:

$$\left(\frac{2{\cdot}667\ c + 8\ h + s - o}{21 \times 1{\cdot}43}\right) \times 100 = L \text{ cubic meters.}$$

There are wide variations in the data chosen in the computation of the calorific value of fuel according to the Dulong formula. Some make use of the simple formula,

$$W = 8000\ c + 34{,}500\ (h - \tfrac{1}{8}\ o).$$

Others make deductions for the hygroscopic water, as under:

$$W = 8000\ c + 34{,}400\ (h - \tfrac{1}{8}\ o) - 637\ w.$$

Others take into account the heat required to evaporate the total water formed during the process of combustion, like Ferrini, who uses the following formula:

$$W = 8100\ c + 34{,}500\ h - 600\ (w + 9\ h).$$

The most accurate method certainly is to use the calorimeter; but the determinations with its use are so troublesome that, for practical purposes, computation from elementary analysis of the fuel will probably be generally retained. The commission rejects the practice of assuming that the oxygen found by analysis should be computed as combining with a corresponding quantity of hydrogen in forming water. It is argued by them that due deductions should be made for the fact that, by the combustion of the hydrogen of the coal, steam is produced, which carries off a certain quantity of heat. They therefore reduce the calorific value of the hydrogen to 28,800 instead of 34,220 calories, which is the average of the determinations of Thau, Andrews, Thomsen, Favre & Silbermann, and Schuller & Wartha. They have therefore put forward the formula:

$$W = 8100\ c + 28{,}800\ (h - \tfrac{1}{8}\ o) + 2500\ s - 600\ w.$$

The theoretical calorific value of a fuel may thus be found from its analysis.

When the question is to ascertain the loss of heat by the gases of combustion, the analyses of the latter must be given. Let it be assumed that they contain k per cent of carbonic acid, d per cent of carbonic oxide, m per cent of methane (CH_4), and r per cent of carbon in the form of soot. In every cubic meter of carbonic oxide, carbonic acid, and methane, there is 0·5395 kilogram of carbon; therefore, one cubic meter of a mixture of these gases contains:

$$\left(\frac{k + d + m}{100}\right) 0{\cdot}5395 + r = A.$$

Calling this expression A, then one kilogram of coal will yield: $\frac{C}{A} = G$ cubic meters of dry gases passing up the chimney. In these gases, there are $\frac{G \times k}{100}$ cubic meters of carbonic acid, $\frac{G \times d}{100}$ cubic meters of carbonic oxide, $\frac{G \times m}{100}$ cubic meters of methane, $\frac{G \times h}{100}$ cubic meters of hydrogen, $\frac{G \times o}{100}$ cubic meters of oxygen, and $\frac{G \times n}{100}$ cubic meters of nitrogen. The specific heat for one cubic meter of the different gases is:

Carbonic acid	138·9
Oxygen	93·3
Nitrogen	91·9
Sulphurous acid	133·4

By multiplying these values with the quantity of gas in cubic meters and with the excess of the temperature possessed by the chimney gases over and above that of the boiler-house, the loss of heat by this source will be found.

There is also contained in the gases aqueous vapor resulting from the combustion of the hydrogen in the coal, which will produce 9 times its weight of water. At 100 degrees Centigrade, this quantity of aqueous vapor contains 637 times the product of calories of heat, and for every degree and kilogram of hydrogen must be added to this 0·475 calorie, so that the total loss of heat from this source may be found.

A third source of loss is the unburnt combustible constituents, carbonic oxide, methane, and hydrogen. Making deductions for the specific heat of the aqueous vapor formed by the combustion of hydrogen and methane, the calorific value of these gases per cubic meter is as follows:

Carbonic oxide	3058 calories.
Methane	8514 "
Hydrogen	2580 "

The determination of the loss of heat through the ashes is found by multiplying the grains of combustible fuel in the ash per kilogram of coal burned by 808.

Bunte gives an example of Ruhr coal containing:

Carbon	81·60 per cent.
Hydrogen	4·21 "
Oxygen	5·48 "
Ash	6·04 "
Water	2·69 "

This coal was burned so carefully that the gases showed by analyses the following composition:

Carbonic acid	6·12 p. c. by volume.
Carbonic oxide	0·89 " "
Hydrogen	0·10 " "
Oxygen	14·21 " "
Nitrogen	78·68 " "

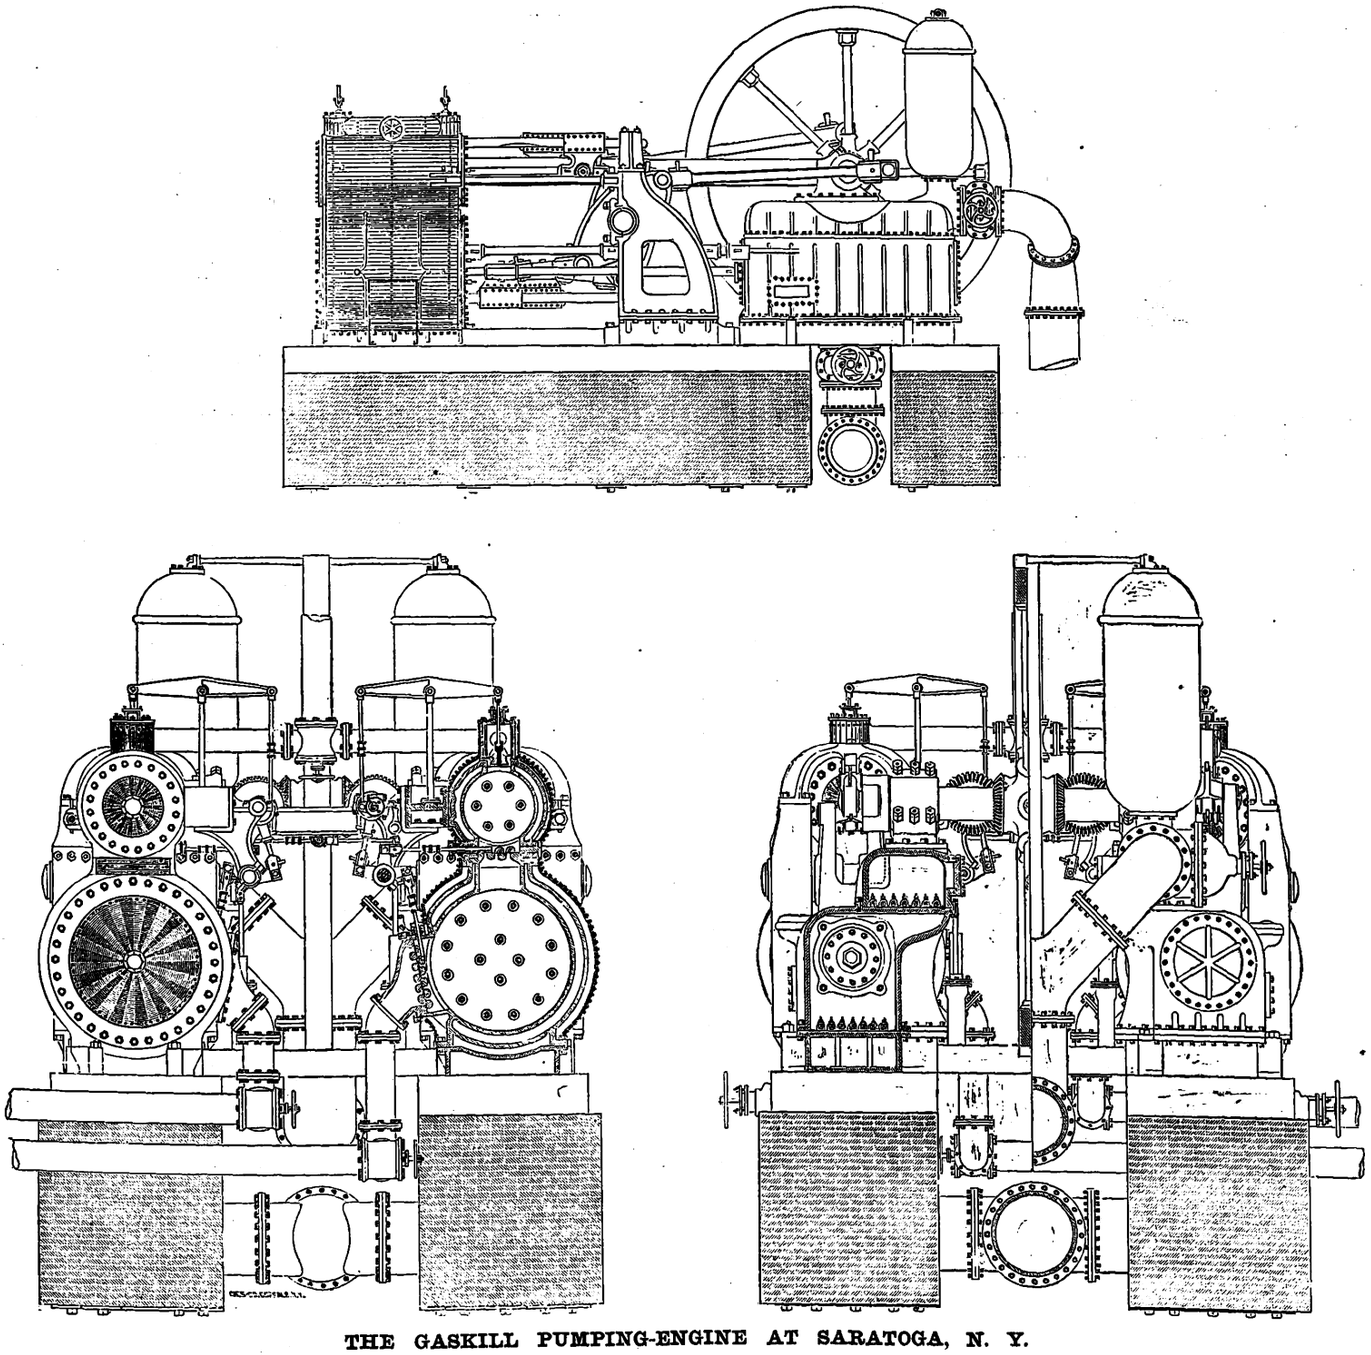
The losses in this case were distributed as follows:

Specific heat of gases	1,492 calories.
Specific heat of aqueous vapor	283 "
Unburnt combustible substances	647 "
Loss in ash	331 "
Total loss	2,753 "

The total heat development of the coal per kilogram, as determined in this case by elaborate calorific experiment, was 8037 heat units, thus showing a loss of 34·25 per cent, the excess of temperature of the chimney gases over mean temperature of boiler-house being 224 degrees Centigrade, and the quantity of fuel burned per square meter of grate surface per hour being 54·5 kilograms.—*Coal.*

FUEL-GAS COMPANY.—Another fuel-gas company, composed of Chicago, Pittsburg, and Westmoreland County capitalists, has been formed. Colonel Archibald Blakeley, its representative, has secured twenty charters for supplying the greater portion of Westmoreland, Indiana, and Armstrong counties with natural gas. The capital stock is $1,000,000, and the company has purchased 2000 acres of land along the Kiskiminetas River, and also controls one of the Murraysville gas-wells. The object of the company is to supply Scottdale, Mount Pleasant, Irwin, and other towns in the vicinity with the natural gas, and it is expected that the company will be in active operation by the close of the winter. It is composed of Milton Weston, Judge John C. Polly, William H. Mechling, and Jonas Mechling, of Chicago; A. M. Sloan, Dr. J. S. Crawford, and Messrs. Johnston and Wallace, of Greensburg; and Colonel Blakeley, of Pittsburg. The company will begin operations shortly near McKeesport.

THE CHECK-WEIGHMAN LAW.—The law compelling the use of cars of a uniform capacity in all bituminous coal mines, the branding of all cars within three months' service, and the employment of a check-weighman, went into effect in Pennsylvania, on the 15th of September. The law regarding the latter is as follows: "The check-weighman shall not be considered a trespasser during working hours while attending to the interest of his employers, and in no manner shall he be interfered with or intimidated by any person, agent, owner, or miner; and any person violating these provisions shall be guilty of a misdemeanor, and upon conviction shall be punished by a fine of not less than $20 and not exceeding $100, or imprisonment at the discretion of the court. Should any weighman or weighmen or check-measurer, whether employed by operators or miners, knowingly or willfully adopt, or take more or less than 76 pounds for a bushel or 2000 pounds for a ton, or willfully neglect the balancing or examining of the scales or cars, or knowingly or willfully weigh coal with an incorrect scale, he or they shall be guilty of a misdemeanor, and upon conviction thereof shall be imprisoned in the county jail for three months."



THE GASKILL PUMPING-ENGINE AT SARATOGA, N. Y.

The exceptional record of the Gaskill pumping-engine at the Saratoga Water-Works has attracted much attention, being the first built after the latest design. It has been the subject of two interesting reports, one by Mr. John W. Hill, M.E., who comments on the results in a paper contributed to the October number of Van Nostrand's *Engineering Magazine*, and the other by Mr. Charles T. Porter.

The engines which we illustrate in the accompanying engravings are horizontal compound, of the type designed by Mr. H. F. Gaskill, of the Holly Manufacturing Company, Lockport, N. Y. Mr. Porter describes the engines as follows:

Each high-pressure cylinder is placed on top of a low-pressure cylinder, between these cross-heads is made by means of a short vertical beam and connecting-links, through which also the force exerted in the high-pressure cylinder is transmitted. A shaft carrying a fly-wheel revolves on bearings which are set upon the delivery-chambers of the two pumps. The two engines are connected through this shaft by means of cranks set on each end of it, at right angles with each other, and connecting-rods from these cranks to the upper ends of the beams. The cranks determine the length of the stroke, control the movements of the pistons and plungers, maintaining those of the two engines and pumps in a constant relation with each other, and give motion to the valve-gear.

The steam is admitted to the high-pressure cylinders by double-seated poppet-valves. A cut-off mechanism is introduced into the motion of these valves, which is adjustable to cut the steam off at any point in the

THE GASKILL PUMPING-ENGINE AT SARATOGA, N. Y.

in the manner shown in our engravings, the object being to obtain a direct and short passage for the steam from the first to the second at each end, and thus avoid the waste of steam of the usual long passages, in compound engines, between the high and low-pressure cylinders. This arrangement requires the pistons of the two cylinders to move in opposite directions, the pressure of steam upon the pistons of each pair being transmitted to the flanges of their pumps in the following manner: The latter is set in line with the low-pressure cylinder, and so receives the thrust produced by the pressure of that cylinder directly. The low-pressure piston is provided with two rods, which are extended to the length of ten feet to the cross-head by which they are connected with the rod of the pump-plunger. Midway in their length, another cross-head is secured upon them, which runs on a guide. The rod from the high-pressure cylinder is keyed into a cross-head corresponding to this. The connection

length of the stroke. The point of cut-off may be fixed by hand, or by the action of the governor when the latter is thrown into gear. The governor is constructed to be operated by changes in the pressure of water in the delivery main, and acts to correct these changes by varying the point of cut-off, and thus the speed of the engine, in accordance with the variations in the demand for water. The communicating valves between the high and low-pressure cylinders and the exhaust-valves are gridiron slides. All the valves are driven by eccentrics, mounted upon two longitudinal shafts turning in bearings sprung from the inner sides of the high-pressure cylinders. These shafts are driven by miter-wheels from the main shaft.

All the cylinders and their heads are steam-jacketed. The water formed by condensation in the jackets is returned to the boilers in the ollowing manner: The jackets blow directly into a small heater. The

Digitized by Google

feed-water is conducted through this heater in a two-inch coil-pipe. A separate pump receives its supply from the bottom of this heater, and sends the hot water forward to unite in the feed-pipe with the new water, which has been already partially warmed in passing through the coil in the heater. This is a restoration to the boilers of that portion of the heat supplied by them to the jackets which had not been imparted from the jackets to the steam in the cylinders. The restoration is effected very well, except that the stuffing-box of the pump has no special provision for retaining hot water, and leaks sufficiently to make an appreciable loss.

There is no provision for preventing steam from blowing along with the water from the jackets into the heater. A valve was put into the drain-pipe, by partially closing which the full pressure was maintained in the jackets, and only a pressure of about twenty pounds was allowed in the heater. This was all that the situation admitted of, and it could not be known how much steam passed with the condensed water into the heater. Had it been practicable to attach an apparatus by which all the steam would have been kept back, and only the condensed water been allowed to pass, it would then have been easy, as it was desirable, by taking the temperature of the feed-water as it entered the boilers, to have known, very nearly at least, the quantity of steam condensed in the jackets. Since, however, the coil feed-water pipe in the heater acted as a surface condenser, and it was impossible to determine how much steam from the jackets was condensed by it, it seemed idle to take this temperature, which would rather lead to confusion than give any information.

The knowledge of the amount of heat imparted by the jackets would alone, however, give an exaggerated idea of the gain from their use, since there can be no doubt that they are most efficient in evaporating moisture contained in the steam at the time when it is passing directly into the condenser. The only satisfactory mode of determining the amount of the gain would be by a comparison of the results of this trial with those of another one, conducted with equal care, in which the steam was entirely shut off from the jackets.

The following are the principal dimensions:

Stroke of all cylinders			36 inches.
Diameter high-pressure		cylinders	21 "
" " "		piston-rods	3 "
" low "		cylinders	42 "
" " "		piston-rods	3·5 "
Clearance high "		cylinder	2·35 per cent.
" low "		"	2·50 "
Diameter of fly-wheel			12 33 feet.
Weight " "			12,000 lbs.
Diameter of main shaft			10 inches.

These are horizontal double-acting plunger-pumps, the plunger working through a diaphragm separating the two chambers, and are constructed on the multiple-valve system. Their dimensions and performance are given in the following table.

During the test for duty and a part of the fire pressure test, their speed very much exceeded that required to supply the demand for water. The excess of water delivered was got rid of partly by opening hydrants and partly through the relief-valve.

The pressure in the supply-chambers was got by the indicator, with a spring showing twelve pounds to the inch. The pencil described the figure shown in a diagram which affords an interesting exhibition of the changes in the pressure as momentum is imparted or arrested in the current of water. The mean pressure, when corrected for elevation, was found to be one and one quarter pounds on the square inch at the center of the plungers, showing the level of the water from which the supply is drawn to be about thirty-four inches above this point.

It is to be observed, relatively to the fluctuations of pressure, both in the supply-chamber and in the delivery main, and also relatively to the motion of the plungers while the valves are closing, that in these pumps this motion, with that of the pistons, is controlled by the cranks, precisely as if it was transmitted through them. The valves are assumed to close only as fast as gravity would cause them to fall, although without doubt the reverse current brings them to their seats more quickly than this. But even on this assumption, the slip is no more than four tenths of one per cent.

The pumps are provided with by-pass pipes and valves, forming, when the latter are open, a communication between the two chambers of each pump. Their function is this: At the instant of starting, the engines are able to exert only a portion of their power, because no steam has yet been admitted to the low-pressure cylinders. The pressure of water is liable to be greater than the steam in the high-pressure cylinders alone can overcome.

In such a case, the by-pass valves can be opened, when the water flows through them into the opposite chambers, the pressure on the opposite ends of the plungers is in a measure equalized, and the engine is enabled to start. As soon as it is fairly in motion, these valves are closed.

They are available, also, when the motion of the engines required to supply the demand for water would be so slow that, on account of the insufficiency of the fly-wheel, it could not be maintained with the desired regularity, or perhaps not at all. Then, by partially opening these valves, the engines are enabled to run faster, and so to maintain their motion satisfactorily, the excess of water displaced by the plungers passing through them into the chambers that are filling.

The principal dimensions of the pumps are:

Aggregate length of the two chambers in each pump	7 feet 6 inches.
" width " " " " " "	2 feet 3 inches.
" hight " " " " " "	2 feet 11 inches.
Capacity of each pump-chamber, in cubic feet	25
Diameter of plunger, inches	20
" " rod	4
Area of plunger, mean of two faces, square inches	307·88
Stroke of plunger, inches	36
Displacement of plunger, in cubic feet	6·41417
" " " in gallons	48

The two boilers furnishing steam are of the horizontal return tubular type, the following being the principal dimensions:

Diameter	66 inches.
Length	18 feet.
Number of tubes in each boiler	87
External diameter of tubes	3 inches.
Arrangement of tubes: horizontal and vertical rows	
Least distance between tubes and shell of boiler	4·5 inches.
Hight of crown of boiler above tubes	24 inches.

Heating surface in both boilers, as follows:

One half the shells, 311; tubes, 2460. Total	2771 sq. feet.
Furnace, width	6 feet.
" depth	5·75 feet.
" length of opening between grate-bars	5 feet.
" " these openings uncovered	4·25 feet.
" width of each grate-bar	1·75 inches.
" width of air spaces	·5 inches.
" square feet of grate area, under both boilers	51·00
" of which the proportion in air space is only	·22

Horizontal flues, as follows:

Three times the length of each boiler	54 feet	
From wall between boilers to chimneys	24 "	
Total		78 feet.
Internal diameter of common flue and chimney		3 "
Hight of chimney above flue		75 "
Square feet of heating surface for each one square foot of grate area		54·3
Square feet of heating surface for each indicated horse-power		14·9

Mr. Porter reports the following results of a test of forty-eight hours.

Boilers.

Coal burned	16,860 lbs.
" " per hour, on each one square foot of grate	6·9 lbs.
Water evaporated	155,961 "
" " by combustion of one pound of coal	9·25 lbs.
Average temperature of feed-water	71·5 deg.
" pressure of steam, by gauge	73·66 lbs.
Number of thermal units contained in one pound of steam	1211·1
Equivalent evaporation from 212 degrees, under one atmosphere	10·916 lbs.
Evaporation per hour from each one square foot of heating surface	1·175 "

Engines.

Average number of revolutions made per minute	19·370
Average piston speed, in feet	116·220
Pressure of the atmosphere, in pounds on the square inch	14·560
Average horse-powers exerted in high-pressure cylinders	109·200
" " " " " low " "	76·550
" " " " total	185 750
Pounds of coal burned per hour	351·000
" " " " horse-power per hour	1·900
Pounds of water evaporated per hour	3250·000
" " " " horse-power per hour	17·500
" " " " hour for each horse-power exerted in the high-pressure cylinders	30·000
Total average back-pressure in high-pressure cylinders, pounds	12·500
Pounds of water per hour accounted for by indicator:	
1st. At point of cut-off in high-pressure cylinders	2061·000
Proportion of the quantity evaporated	·634
2d. At point of release in low-pressure cylinders	2880·000
Proportion of the quantity evaporated	·886
Temperature of the steam in all jackets, degrees	318·700
" " high-pressure exhaust (average)	204·000
" " low " "	153·000

Pumps.

Number of double strokes of each plunger per minute	19·3700
Mean velocity of plunger, in feet, per minute	116 2200
Number of valves acting together	84·0000
Diameter of each valve-opening, inches	1·3125
Total area opened by valves, square inches	113·6000
Lift of each valve, inches	·3125
Mean velocity of water through valves, in feet, per second	5·2500
Weight of each valve, pounds	·5625
" " " " for each one square inch of opening, pounds	·4160
Resistance to current on each one square inch of opening, pounds	·2600
Total loss of efficiency in pounds on square inch	(·416 + ·26) × 2 = 1·3620
Mean excess of pressure in the delivery main, pounds on square inch	84·5700
Proportion of power lost in passage through valves	·0160
Time occupied by valves in closing, seconds	·0400
Motion of plunger while valves are closing, inches	·0700
Proportion of stroke lost in closing of both admission and delivery valves	·0040
Net delivery from both pumps per double stroke, gallons	190·0000
Net delivery from both pumps per double stroke, pounds	1584·0000
Delivery per day at eighteen revolutions per minute, gallons	4,924,800·0000
Number of double strokes made in 48-hour test	55,779·0000
Net foot-pounds of work done on each double stroke	309,338·0000
" " " " " " by consumption of 100 pounds of coal	102,340,000·0000

In a duty trial extending over twenty-four hours, Mr. Hill gathered the following data:

In the following table are recapitulated the averages of all data and totals for duty trial:

Duration of trial, hours	20
Average pressure by engine gauge, pounds	74·25
Average vacuum, inches	27·295
Average temperature of injection, Fahr	56·225
Average temperature of overflow, Fahr	71·125
Average temperature of feed-water to boilers	169·175
Average pressure by gauge on force-main, pounds	95·06875
Difference of levels, center of pressure-gauge and source of supply, pounds	0·12965
Revolutions in twenty hours	21,449
Revolutions per minute	17·8742
Piston speed per minute, feet	107·2452
Total coal burned, pounds	6,750
Calculated discharge of pumps per revolution, gallons	191·923
Actual estimated discharge of pumps per revolution, gallons	187·125
Weight of water per gallon at 56 Fahr., pounds	8·33
Contract delivery at 18 revolutions, gallons	4,000,000
Actual estimated delivery at 18 revolutions, gallons	4,850,280
Excess over contractor's guarantee, per cent	21·257
Contract duty per 100 pounds coal	80,000,000
Conventional duty as per trial	112,899,988 104
Excess over contractor's guarantee, per cent	41·125
Net absolute duty, as per trial	108,793,535·3
Excess over contractor's guarantee, per cent	36

The following are the totals and averages of a daily report made by

Digitized by Google

David L. Holland, engineer of the water-works, for the week ended September 8th:

Total revolutions—6 A.M. to 6 P.M.	50,060	
" " —6 P.M. to 6 A.M.	37,460	
" "	87,520	
Coal burned from 6 A.M. to 6 P.M.	18,000	lbs.
" " " 6 P.M. to 6 A.M.	17,200	"
Total coal	35,200	"
Average water pressure	113	"
" steam pressure	70	"
" vacuum	28 1	"
Total gallons pumped	16,716,270	
Average duty	103 040 851	
Maximum duty	106,413,967	
Minimum duty	100,448,140	

Mr. Porter speaks in the highest terms of approval of the workmanship of the machinery. He, however, expresses the opinion that the fly-wheel is insufficient, and believes that the fluctuations of pressure, which do not appear to exceed five pounds, could be reduced by using a fly-wheel eighteen feet in diameter. He advocates, also, in order to prevent in a greater degree the transfer of heat from the steam in the steam-pipe to the condenser without doing work, the employment of higher piston speed or moderate superheating of the steam.

DIAMOND MINING IN THE PROVINCE OF MINAS-GERAES, BRAZIL.—II.

The region in the vicinity of Diamantina forms a vast plateau through which a great number of rivers pass in deep cañons. The diamonds, which seem to come from the chains of mountains beyond the plateau, might therefore have been spread over another surface at the time the rivers were at the same level. Those which have been thus deposited on that part of the ground not removed by later erosion have remained, and this may be the origin of those deposits which are now found at great altitudes. In any case, all the deposits thus found in the beds of the rivers, as well as those on the banks or on the plateaus, are alluvial. Of all the rivers in the region, the most important and the richest is the Jequitinhonha, at least in its upper portion. The tributaries of this Jequitinhonha River from the right are very poor, while those entering from the left bank are very rich; for instance, the Rio Caëthémerim, the Rio Pinturo, and particularly Ribeirao-de-Enferno. These have their source in the chain of mountains alluded to. This fact gives strong evidence that the diamonds found to-day come from this chain above the plateau of Diamantina, and this leads me, says M. de Bovet, to allude to a special deposit, the only one of its kind, so far as I know, which does not possess any of the characteristics of an alluvial deposit. At S. Jean-de-Chapada, one of the highest points of the chain, diamonds have been extracted from layers of argillaceous schist interstratified with quartzite. These shales are distinctly stratified, and seem without any doubt to be in place, being produced by the decomposition of schists. Formerly, there were at this point extensive workings, now abandoned. There is an open cut more than 180 feet deep at some points, in which there are two small springs, one of them the source of the Rio Duro, and the other of the Rio S. Joao. A study of the topography leads me to believe that this deposit was a lenticular body in beds of quartzite. I have seen the shale taken out in my presence, and, after washing, it gave some diamonds, and with them were the same minerals which accompany the diamonds in the gravel, though not rounded, and in very much smaller quantity. This is natural, as it came from the deposit in place, and therefore had not been submitted to any natural mechanical separation. It seems that this is an original deposit, from which the diamonds were derived. It may be noted that at Grao Mogol, diamonds have been found in quartzite beds; but with the exception of the San Joao shales and the Grao Mogol quartzite, the diamond has never been taken from workings in other than alluvial deposits.

THE EXTRACTION OF THE DIAMOND.

So far as can be judged from the traditions which have come down to us as to the method employed in working the river-beds in former times, it does not seem that any notable progress has been made since then, except that pumps have been introduced. To-day, as it was then, the diamonds are extracted by hand. The river workings can not be opened without diverting the river from its bed, which is generally done by allowing it to pass into a canal. This canal is constructed, whenever possible, on one of the banks, by building a dam of rock; but generally, for its greatest length, it must be made of planks and carried on trestles.

When the point at which the workings are to be made has been chosen, the river is dammed above and below, and it is between the two dams that the work is done. At Diamantina, these dams are generally very well constructed. The workings are pumped dry by pumps driven by means of undershot wheels placed in the canal itself. The top sand is removed entirely by hand by means of flat scoops, carrying about thirty pounds, which a man places on his head and dumps into the canal. When the sands have been removed and the layer of rocks has been reached, the rock is blasted with powder and the small pieces are carried off in the same way. At Acaba Mundo, about 280 men were at work. Eighteen filled the scoops, which some 260 were employed in carrying off, so that, during a day's work of ten hours, about twelve hundred tons were removed, being lifted from twenty to twenty-five feet, and carried away a distance of from two hundred to two hundred and fifty feet.

The workmen are almost all of them negroes and slaves. They are divided into three or four gangs. The first one who reaches the canal dumps his sand, and then does not stir until the last one of the gang has done the same thing. All of them sing two or three verses of some negro song, and then rush back to the workings, where they have their scoops reloaded. This may be very picturesque, but it is very slow work, and very extravagant. The figures given above refer to work in the beginning when the diggings are not yet extensive, and the men do not get in one another's way; but as the pit deepens, the large number of men disturb one another, and they must form a chain along which the scoops are passed. This, of course, reduces the effective work considerably. All this labor is done in a country from which all the timber has been cut, and where the soil is exclusively sand, which does not retain the water, so that the slightest rain increases the volume of water in the river very much. As soon as the rainy season begins and the first storm has come, all of the dams are carried away, and in a few days the excavations made during the dry season are filled up. The dry and the wet seasons are fortunately very distinctly separated; and as soon as the latter has ceased, four months may be counted upon, from the middle of May to the middle of August, during which not a drop of rain falls. During this very short period, and with manual labor, it is evident that no great stretch of the river-bed can be worked, and that the extent of a working is still more restricted when the gravel must be sought at a great depth. The miners at Diamantina believe a depth of eighty feet to be the limit which they can reach. Those portions of the canal which are made of timber are always removed prior to the beginning of the rainy season.

TREATMENT OF THE GRAVEL.

As the nature of the workings in the river-bed is such that work must go on as rapidly as possible until the day when it is believed prudent to remove the canal, no attention whatever is paid during the dry season to getting the diamonds. All that is done is to remove to a place of safety the greatest possible quantity of the diamond gravel. When the gravel contains clay, it is first puddled in a shallow basin. The workmen walk about in it and agitate it with hoes, the water carrying off the fine mud. The rest goes to the washer. This is a small basin, about three feet square, one end being open, while the other and the sides are from twelve to sixteen inches deep. The bottom is slightly inclined toward the open end. Immediately below is a second basin full of water, in which the workman stands knee-deep. When the gravel has been placed in the upper basin, the workman takes up water with a scoop, and throws it against the gravel. Thus the lighter sands are carried off. The larger pieces are removed by hand. The rest is washed in a pan. This must be done very slowly by skilled men. The diamond is not found at the bottom of the pan, as gold is. On the contrary, it appears on the surface. After having agitated by a peculiar movement the sand on which he is working, the washer slowly allows the excess of water to flow off, and at a glance sees the diamond which he has brought to the surface. Sometimes, white sand is mixed with the gravel, in order to enable the washer to see the diamond more distinctly. It is not probable that this part of the process can be replaced by any mechanical contrivance.

THE STRENGTH OF WROUGHT-IRON STRUTS.

At a meeting of the American Society of Civil Engineers, a paper by Mr. James Christie was read on Experiments on the Strength of Wrought-Iron Struts. These experiments were made at the Pencoyd Iron-Works, for the purpose of determining the comparative resistances to compression of long and short struts of rolled angles, tees, beams, and channel sections. The specimens were tested by four different methods, namely, with flat ends between parallel plates, to which the specimen was in no way connected; with fixed ends, or ends rigidly clamped to parallel plates, the plates substantially forming flanges to the specimen; with hinged ends, or both ends fitted to hemispherical balls and sockets or cylindrical pins; with round ends, or both ends fitted to balls resting on flat plates. The specimens varied in length from six inches up to 16 feet, and were selected to obtain a uniform character of material. The paper gave tabulated results of 299 experiments, and these results are illustrated by a number of diagrams. There were also results given of a number of tests of welded tubes. The general conclusions drawn from these experiments were as follows ($\frac{l}{r}$ being length divided by least radius of gyration): When struts are short, say $\frac{l}{r}$ below 20, there will be no practical difference in the strength of the four classes, so long as reasonable care is taken to keep the center of pressure in the center of the strut. Hinged-ended struts vary all the way from round-ended up to flat-ended in strength. If the hinges are pins of substantial diameter, well fitted, and exactly coincident with the axis of greatest resistance of the strut, the strength of the strut will be fully equal to that of a flat-ended, but, considering the impracticability of maintaining this rigid accuracy, the average hinged struts as compared with flat-ended will fall in strength as the length is increased until $\frac{l}{r}$ is about 250, when they will average one third less resistance than flat-ended. From this point, they will gain comparatively until $\frac{l}{r}$ becomes about 500, when both classes will be practically equal. Fixed-ended struts gain in comparative resistance, from the shortest lengths upward, until $\frac{l}{r}$ becomes about 500, when they are twice as strong as either the flat or hinged-ended.

Round-ended struts continually lose in comparative resistance as the length is increased. When $\frac{l}{r}$ is above 340, they will be half as strong as hinged-ended, and when $\frac{l}{r}$ is above 160, they will have only half the strength of flat-ended.

The iron from which the tests were made exhibited the following resistances to direct compression, being the general results of several tests of small section, fifteen inches long, and secured in such a manner as to prevent lateral flexure:

With 30,000 pounds pressure per square inch, incipient permanent reduction of length was observed. With 35,000 pounds pressure per square inch, failure of elasticity occurred, and marked permanent reduction of length. With 50,000 pounds per square inch, a permanent reduction of length of three per cent occurred. With 75,000 pounds, a permanent reduction of ten per cent; and with 100,000 pounds pressure per square inch, a permanent reduction of twenty-eight per cent of the length.

The paper was discussed by Messrs. Theodore Cooper and Charles E. Emery, who both expressed the opinion that these experiments were of very great value, being made with material of uniform character, and in such a way that comparisons could be made directly between the different methods adopted in testing.

FURNACE, MILL, AND FACTORY.

The Lidgerwood Manufacturing Company, No. 96 Liberty street, New York, manufacturers of hoisting machinery, has determined to be represented in Baltimore, and hence has placed an agency for its goods with Messrs. Morton, Reed & Co., who are favorably known to the trade of the North and South.

The Crane Brothers Manufacturing Company, of Chicago, is building for the Charlotte Iron-Works, Rochester, N. Y., a complete blast-furnace hoist containing some new improvements. The machinery department of the works is running full.

Eckert's furnace, No. 1, at Reading, has chilled, and during the past few days and nights a force of men has been vainly trying to break up the solid mass within. Chipping and prying have been almost useless, so hard has it become, and several blacksmiths are kept busy sharpening tools. The furnace is 57 feet high, and now contains 38 feet of chilled material. It will require several months before it is again in running order. The remaining furnace has been idle also, but is now blown in.

The Lechner Manufacturing Company, Columbus, O., manufacturer of elevating and conveying machinery and roller detachable chain belting, has made a shipment of a chain elevator to the New York City Plate Glass Company, at Tarentum, Pa., to be used for elevating sand; and has also furnished S. J. Meeker, Newark, N. J., with roller chain belting, etc. In addition to this, it has furnished the Columbus & Hocking Coal and Iron Company, Columbus, O., with another chain elevator for its mine at Longstreet, Ohio, for elevating coal.

The articles of association of the Chartiers Iron and Steel Company, Limited, have been placed on file in the recorder's office at Pittsburg. The capital is $60,000, and has been paid in as follows: John C. Kirkpatrick, $25,000; David A. Carter, $12,500; Barker C. Wilson, $12,500; and John Henry, $10,000. The officers are: J. C. Kirkpatrick, Chairman; D. A. Carter, Secretary; and B. C. Wilson, Treasurer.

The Indianapolis *News* of the 20th ult. reports as follows: The new steel rail mill ran through several blooms yesterday, having begun operations again the day before. The machinery worked so well, and all the operations promised to be so economical, that Secretary Jones told the reporter that it was not improbable that the company would make contracts for a regular supply of blooms, and continue in operation permanently. Not much could be made at it at the present prices of steel rails, but he was so well satisfied that the work could be done so much more cheaply by their improved processes than other mills could do it that there would at least be no loss. Since the last notice in the *News* of the operations of this great enterprise, Mr. Lentz has added some minor improvements that help the automatic work considerably. One of these is a combination of levers or lifters that turn the hot bloom on the hooker rollers, as they raise it to the upper rolls. This saves some trouble and uncertainty about getting the bloom into proper position to pass through the rolls. The two 1 300-pound blooms which the reporter saw rolled out into 60-foot rails met with but two or three slight hitches from the roughing rolls to the saw, and the worst of these was the result of an oversight that was soon remedied.

The guide mill, connected with the Portland Rolling-Mills, at Portland, Me., was burned October 9th.

A dispatch from Cleveland says that the scheme of reorganizing Brown, Bonnell & Co., the iron-works company of Youngstown, has failed, and an effort is making to form a new company, with a capital stock of $1,200,000, and to assume all the assets and liabilities of the old company.

The new water-jacket furnace at Reading, Pa., owned by Henry S. Eckert, has been in blast about one week, and up to this time the result has been very satisfactory; thirty tons of iron are made daily, but it can be increased to forty. This is said to be the only furnace of the kind in the United States. The jacket surrounds the furnace to the hight of 19 feet 9 inches; it is made in sections, so that if an accident should occur to either section, it could be replaced. Between the outer and inner plates of the upper section, is a thickness of five inches of water, and in the lower section, four inches. The fresh water is constantly running in above, and is allowed to flow off below through pipes.

GENERAL MINING NEWS.

ARIZONA.

GILA COUNTY.

Miners at Pioneer have struck against a reduction of fifty cents a day. It is said that they will not permit any one to work for less wages than they received.

GRAHAM COUNTY.

ARIZONA COPPER COMPANY.—The Longfellow and Metcalf claims, which, with Coronada and Copper Queen, are the principal properties of this company, are actively worked, and sundry improvements are in progress which will tend to the more economical working of the company's properties. Four new smelters are to be erected.

DETROIT COPPER COMPANY.—The company has four mines adjoining, and west of the Longfellow mine. The daily shipments of ore amount to between 50 and 60 tons, which yields an average of 25 per cent copper. The mines are worked by a series of tunnels, the ore being mainly stoped out from these tunnel levels. Two shafts have been sunk on the Copper Mountain mine, one of which, a main working-shaft, is down about 180 feet. The gangue of the ore in the Copper Mountain carries enough iron to flux the carbonate ores of the Arizona Central and Lower Yankie. The reduction-works of the company are at Morenci, on the Frisco River, some six miles distant from the mines. The company has two water-jacket furnaces—one Rankin & Brayton and one Fraser & Chalmers. But one furnace is blown in at a time, the other being kept in reserve in case of accident. The company contemplates at an early day putting in another furnace, and running two constantly. The average daily output of copper matte is at present between 9000 and 10,000 pounds. The copper matte is shipped to Ansonia, Conn., where it is refined and is sold in the market as the Anchor brand.

CALIFORNIA.

AMADOR COUNTY.

PLYMOUTH CONSOLIDATED.—Mr. W. Van Norden writes us that the company was organized June 1st, 1883, by the consolidation of several properties, and has paid dividends regularly each month. About two millions of dollars in gold have thus far been taken from the mine. The mine is down about 1400 feet, and has a large quantity of ore in sight, having four levels open, and each but little worked. The company has kept much ahead of its needs in development. The vein is from 20 to 54 feet in width, of mixed gray and white quartz—called "ribbon quartz"—and with a small percentage of sulphurets. The gold mills freely. The shaft is vertical, three compartment. There is steam-power to raise 500 tons per day. The mills are run by water, and have a capacity of 120 stamps. The rock runs from $14 to $16 a ton. The production is about $80,000 per month. One hundred and twenty stamps are running at times, and part of the time 80, until the water rises in the fall. The cost of plant, including stamps, was about $350,000.

MONO COUNTY—BODIE DISTRICT.

The Bodie *Free Press* says that the Noonday, North Noonday, and Red Cloud Consolidated mining companies, together with all real estate belonging to the companies respectively, will be sold at public auction on the premises by the assignee in insolvency, Irwin C. Stump, on Monday, November 19th, 1883.

BODIE CONSOLIDATED.—The official report for the week ended September 29th shows: Ore crushed, 164⅛ tons; average assay value of pulp, $50.45; of tailings, $5.87.

STANDARD CONSOLIDATED.—The mill has resumed operations. The new engine, which takes the place of the old one, was built at the Union Iron-Works, in San Francisco, and is one of the best obtainable. It is of about 170 horse-power, and the cylinder is 20 by 36 inches. While the new engine was getting into place, the boilers were overhauled and placed in a condition for a protracted season of usefulness. It takes about seven cords of wood each twenty-four hours to keep up the fires in this twenty-stamp mill. Every thing is now in excellent order.

HOMER DISTRICT.

MAY LUNDY.—It is reported that this mine has passed into the hands of an English syndicate, which proposes to develop and work it to its fullest capacity. Heretofore, says the San Francisco *Stock Report*, it has been worked during the summer months only, and even then the ore was run down a 3000-foot tramway to Lake Cañon, and then hauled three miles on wagons to a rude ten-stamp mill. The mine has already shipped something over half a million dollars in gold, and the average yield has been a fraction over $50 to the ton. The ore is free milling. The English company contemplates a deep tunnel over 10,000 feet in length. Desiring to run through its own ground, and to reap the benefits of any discoveries resulting from its enterprise, it is understood that it has purchased, or is to purchase, all the properties along the line of the tunnel. This adit will pass 3000 feet vertically beneath the croppings of some of these properties. The lower levels of the mine make a far better showing, both as to quality and quantity of ore, than the upper workings. Three tunnels or adits have been run—the upper tunnel, 100 feet from the surface, following the vein 90 feet through the

Digitized by Google

crest of a cross-ridge; the second being 270 feet from the surface and 493 feet in length; and the third nearly 600 feet beneath the surface and 899 feet in length—all following the vein.

CANADA.

PROVINCE OF MANITOBA.

It is stated that some English capitalists are considering a proposal to invest largely in mining property in the Lake of the Woods section.

ONTARIO.

A number of American capitalists, according to recent reports, propose to form a company with sufficient capital to enable them to erect crushing and concentrating mills, with a view to the utilization of the waste phosphate rock which so rapidly accumulates about the Ottawa County mines. These gentlemen are the holders for Canada of the patent for Paddock's pneumatic ore separator, and they profess to be able to utilize all rock containing 75 per cent down to 20 per cent of phosphate, and by means of crushing and contracting to bring it up to 85 per cent standard.

ALBERTA.—This company has applied for supplementary letters patent increasing its capital stock from $50,000 to $2,000,000.

COLORADO.

ARAPAHOE COUNTY.

HARRIS.—At a meeting of directors recently held in Denver, it was decided to increase the capacity of the smelter to 150 tons of ore per day, the work to be completed within the next six months. During the interval, the present works wil be run to their fullest capacity, which is from fifteen to twenty-five tons per day.

GILPIN COUNTY.

CALIFORNIA.—The shaft is about 1600 feet deep, and sinking as rapidly as possible to gain a depth of 2000 feet. In the 1400-foot level, a body of ore was recently struck over eight feet solid pay, which is running an average of ten ounces of gold per cord under the stamps, and smelting ore, of which there is a large streak over $150 per ton. The last clean-up from the seventy-stamp mill running on this ore was over 300 ounces of fine gold.

WHITING.—The lessees have begun drifting east and west at a depth of 250 feet in the main shaft of that mine. Enough ore is raised to keep from five to ten stamps running. The mine is now more than paying current expenses in doing the development-work.

GUNNISON COUNTY.

EASTMAN & SHORT CONSOLIDATED.—The concentration-works at Tomichi were burned to the ground recently. The loss is reported to be from $35,000 to $40,000. No insurance.

HINSDALE COUNTY.

CROOKE MINING AND SMELTING COMPANY.—The Ute and Ulé keep up their regular production of about thirty tons per day. The principal work is done in the lower levels of the Ute, although some active development is going on in the Ulé. The concentrator at these mines is running in full blast, and is kept busy concentrating the Ute and Ulé ores, and the ores from several neighboring mines.

INDEPENDENCE.—Work is vigorously prosecuted, and the contract for 1000 tons with the Mingo Smelting Company will shortly be filled.

LAKE COUNTY.

The question of giving the Stamm gas smelting process a practical test at Leadville is again agitated with good prospects of success.

ARGENT.—The Vining mine, on Rock Hill, one of the properties of this company, is looking very well, having undergone great improvements. Recent work toward the southwest has carried developments beyond the unfavorable area, and there is now disclosed to view a quite regular ore-chute. The strength of the ore-body is demonstrated by a stope about seventy feet square, while the breast of ore shows for nearly an equal length, with a thickness ranging from one to five feet. The shipments average about six tons of ore a day, all of fine grade, which is sufficient to meet the expenses of the mine, and leave a surplus of from four to eight hundred dollars a month.

BROOKLAND.—The capital stock has been increased from $1,500,000 to $2,000,000.

CHRYSOLITE.—The lessees of the different portions of the old workings of the mine are working with varied results. The lessees of Muldoon shaft, situated on the north side of the head of East Seventh street, have abandoned the hope of finding mineral on the contact already pierced, and have resumed the sinking of the shaft. At present, the workings are in porphyry at a depth of 160 feet.

CUMMINGS & FINN.—The Grant Smelting Company has just purchased this smelter at Leadville. It is the largest smelter in the carbonate camp, having a capacity of about two hundred tons a day. The property is to be turned over to the Grant Company next month. The purchase is the result of the increasing mineral output of the State, and although the Grant works at Denver are treating 300 tons daily, yet the supply has been increasing rapidly on the company's hands, so that it became absolutely necessary either to enlarge the Denver works or buy or build additional works elsewhere.

EVENING STAR.—The company has nearly one hundred thousand dollars on hand, and no indebtedness. The pumping machinery for the upper shaft is all in place and paid for. The enlarging and retimbering of the shaft is completed within about one hundred feet of the surface, and will be finished in a fortnight. About two weeks more will be consumed in getting the pumps in working order, so that it is anticipated that by the first week in November the sinking of the shaft will again be in progress. The present depth of the shaft is 411 feet, and it is calculated to sink it to a depth of six hundred feet. At the McHarg shaft, the sinking of the sump to greater depth has been taken up. The cutting out of the station has disclosed the mineral vein, which has a thickness of about thirty-four inches of fine sand ore. Some of this mineral has been shipped to the smelter, and returned seventy per cent in lead and nineteen and a half ounces in silver to the ton. A drift will soon be commenced on the strike of the vein, and the extraction of ore will immediately follow. The ore-vein seems to be improving in strength and grade to the southward.

GLASS-PENDERY.—The property is shipping about twenty-five tons of ore a week. The mineral averages twenty per cent in lead, and contains from fifteen to twenty ounces in silver to the ton. The ore also carries a large percentage of iron, constituting it a most desirable ore.

HARRISON.—The works are increasing and improving by the addition of a large roasting-furnace, designed for desulphurizing the sulphide ores at present produced by a number of the mines in California gulch.

HIGHLAND CHIEF.—A meeting is to be held at Leadville shortly, to discuss the present condition of the company. It is evident, says the Leadville *Herald*, that the company can not pay interest or redeem its bonded indebtedness, and that the property will revert to the bondholders pro rata to the amount of bonds they possess. As the bonds expire at an early day, the prospects are, that the stock of the company will soon be valueless, and that the bonds alone will represent interest in the consolidated property. There is but a very small interest in shares out that is not represented by a corresponding amount of bonds. The indebtedness was incurred in working the property and supplying it with machinery and buildings, and afterward in unsuccessful exploration and development-work. The company possesses about twenty-five acres of promising territory, of which an area of only three fourths of an acre has been opened and thoroughly explored. Three shafts on other portions of the company's ground have been sunk to mineral, but no drifting has been done from any of them.

LEADVILLE CONSOLIDATED.—The mines of this company are said to be looking better than at any time during the past six months. During the month of September, a lot of ore of seventy tons was shipped from the Carbonate mine, averaging ninety-eight ounces to the ton. Another lot of about sixty tons is at the smelter, estimated to average one hundred ounces to the ton.

LITTLE JOHNNY.—Owing to litigation, this mine, situated on Breece Hill, was closed down for some months until within a few days, when work was again resumed. The first ore has been hoisted, and the mine will be in a position to ship from ten to twenty tons of ore a day.

LITTLE PITTSBURG.—The monthly expenses range from $8000 to $9000. The principal work in progress is carried on in the Dives and northern portion of the company's claims. The old workings of the mine are gleaned over by miners working on tribute. Included in the new work to be undertaken this month is the cleaning out of No. 10 shaft, and the extension of the drift to the northward on the west side line of the Little Pittsburg claim.

PARK COUNTY.

WESTON.—The company is building a mill at the mine in Mosquito Gulch, of sufficient capacity to accommodate the entire product.

WYANDOTTE.—Contracts have been let for a cross-cut tunnel at the base of the mountain, tapping the vein about 200 feet below the present workings.

PUEBLO COUNTY.

COLORADO COAL AND IRON COMPANY.—A dispatch to the Denver *Tribune* says that the first run of spiegeleisen was made at Bessemer recently, and eleven tons of this valuable material were turned out. A practical test of the new goods has been made in the converters. The home-made spiegel and iron worked to a nicety. The first run of steel rails from the new goods was a success.

SAGUACHE COUNTY.

BUCKHORN.—One of the most wonderful mineral discoveries on record, says the *Chronicle*, was made in this mine on Crystal Hill recently. In the process of developing the mine, caves were discovered varying from a foot to several feet in diameter and many feet in extent, possessing walls of solid, rich mineral.

SAN JUAN COUNTY.

SAMPSON.—The mill is almost completed and will be started up soon.

SUNNYSIDE EXTENSION.—An important strike has been made.

DAKOTA.

BATTLE CREEK GRAVEL MINING COMPANY.—The properties of this company have passed into the hands of Messrs. E. L. Sawyer, Daniel Ferguson, and Peter Johnson, subject to redemption by the company at any time within one year from the date of the sheriff's sale. Arrangements will be speedily made for extensive work. A large amount of gold has already been obtained, and it is alleged that plenty of money could have been made if it had been properly worked.

FAIRVIEW.—The mill has started up on gravel from the Hill claim, Blacktail Gulch.

FATHER DE SMET.—The superintendent reports for the week ended September 25th: At the mine, every thing is going ahead well without any drawbacks. Golden Gate south header shows no change, the face looking as well to-day as it did a month ago. We shall begin breaking out across the ledge soon and get it in shape for stoping. East cross-cut, 3d level, is now out about 69 feet, 43 feet having been run since the present work began. So far, we have cut through a ledge about 20 feet in thickness, which, I think, is part of the ore-body in Cook's chamber, 2d level. As soon at practicable, we shall open out both ways on it and get in shape for a stope. The quality is mixed somewhat, but I think it will average a little better than the ore now milled. The face of the cross-cut is now in slate, and I expect no change until it strikes the Golden Gate ledge. The mill is doing good work so far this run. For the week ended September 30th: Ore extracted from first level, 1000 tons; second level, 900 tons; third level, 845 tons. Ore milled, 2700 tons. Golden Gate east cross-cut, third level, is in 80 feet, and Golden Gate south header, second level, is in 50 feet. For the week ended October 1st: Ore extracted from first, second, and third levels, 2745 tons. Ore milled, 2700 tons. Golden Gate east cross-cut, third level, advanced 18 feet. Total length, 80 feet. Golden Gate south header, second level, advanced 8 feet. Header in 50 feet.

JULIA.—This company has filed articles of incorporation. It intends to develop the Julia and other mica mines in the Black Hills.

GEORGIA.

The supply of water has increased, and most of the mills at the mines in Lumpkin County have started up. The work of development at the mines continues with favorable results.

MEXICO.

From a letter, written by a correspondent of the Mexican *Financier*, from Pachuca, we learn that the Progreso hacienda is at last in full blast. It is reported that the Encino mine is to start to work at full blast very soon. The prospect, Alta Gracia mine, has got its large malacate all up and in running order, and the shaft is sinking.

The Pachuca River Concentrating Company's works shut down a few days ago for a couple of weeks, till the new machinery arrives. A sale of one hundred shares of this company's stock was reported the other day at the rate of $15 per share. The par value is five dollars, U. S. currency. At Santa Rosa, the Schley Mining Company, of New York, owns several splendid mines; the Ida, Robert E. Lee, Washington, New York, La Reina, Savannah No. 1, Savannah No. 2. Of these mines, the Ida, La Reina, Robert E. Lee, and both Savannahs are in paying ore, and these ores are not in pockets, but in true fissure-veins, which, when worked on a large scale, will pay very profitably. All that is now wanting in this district is a good reduction-mill, as the ores have now to be shipped eighteen miles to be reduced. The old Capula mine has eighteen different large lodes coming into it; but at present, it is lying idle. The Santa Teresa Company is a promising property, but badly handicapped, it is said, for want of funds.

MICHIGAN.

The product, of the mines mentioned, for the month of September, is as follows:

Digitized by Google

CALUMET GOLD AND SILVER MINING COMPANY.—The company is exploring on sections 21 and 29, town 48, range 47, which property lies to the north and northeast of the Ropes property.

ERIE.—Operations have entirely ceased, and it is rumored that a reorganization of the company will be effected. The cause of the trouble seems to be that not enough capital to work the mine properly was available.

HYDRAULIC POWER COMPANY.—The company was organized with a capital of $200,000. It has recently been increased to $300,000. The work done will cost $300,000, and when completed will effect a saving of $50,000 per annum to the Chapin and Ludington companies.

NORTHWESTERN.—Shipments are regularly made. The mine is supplied with adequate machinery, and bids fair to become a very large producer.

OHIO.—A depth of about 250 feet has been reached by the diamond drill at work on this tract, and it is expected to strike the ore-body shortly.

PITTSBURG & LAKE SUPERIOR.—A strike has been made about a quarter of a mile south of the Palmer mine workings. At a depth of 220 feet from the surface, the diamond drill encountered ore, and has passed through 22 feet of it. The ore is of a hard variety, and is said to be of excellent quality.

ROPES.—The experiments made have been so successful that the company intends to erect a forty-stamp mill.

MONTANA.

DEER LODGE COUNTY.

GRANITE MOUNTAIN.—The recent discoveries have been so favorable that the company has decided to work the mine on an extensive scale and erect a sixty-stamp mill next year. Until recently, the operations in the main tunnel, prosecuted at great expense for a thousand feet, were so unfavorable that they were on the point of stopping work.

SILVER LION.—This recent discovery has been bonded. About fifteen tons of ore are on the dump that will average about 200 ounces. This ore will be shipped to Denver for reduction.

TIDAL WAVE.—This mine is the oldest discovery in this district, and has been developed to a greater extent than any other. It is opened by two tunnels which have been tapped by a shaft, thus giving the mine a good ventilation. A large pocket or chamber was struck lately. The ore will average over 200 ounces to the ton.

MADISON COUNTY.

The erection of a twenty-ton smelter in Tidal Wave District has induced the owners of a number of claims to prosecute work vigorously.

BROADWAY.—Recent reports state that this property, through extravagant management, was put under a cloud about a year ago, but as soon as a few attachments now resting on it are raised, the mill and mine will again be started.

SILVER BOW COUNTY.

It is stated that the transportation of copper ore from Butte to Baltimore costs $40 per ton. Wood costs $6.50 per cord, and salt, of which enormous quantities are used in the mills in the process of separating, costs $5 per ton in Ogden, Utah, and the railroad charges are $25 per ton for transportation.

NEVADA.

ESMERALDA COUNTY.

NORTHERN BELLE.—Considerable fair-grade ore is obtained at a small expense from the sorting over of the waste-dumps. Five stamps of mill No. 2 are now engaged on custom ore, consequently but 23 tons of ore from the mine are delivered daily, that amount being amply sufficient for the other fifteen stamps.

EUREKA COUNTY.

EUREKA TUNNEL.—This company has been attached by F. W. Chite, of San Francisco, for $36,000, and by O. N. Hansen for $300. Suit was also begun against the company by the White Pine Bank of Eureka for $5391.

STOREY COUNTY—COMSTOCK LODE.

On September 28th, at a distance of about 21 feet, the Union west cross-cut had not reached the vein. There is a slight increase of quartz in the face. The last streak of quartz that was cut had swung around (together with the stratification) until it was parallel to the cross-cut. Whether the vein has swung with the cross-cut is the question which is at present puzzling the management and the holders of securities. The ground showed indications of water at one time, and the Burleigh drill was sent ahead until the ground became drier and the possibility of encountering a flow lessened.

IMPERIAL.—Work will soon begin in the old upper levels for the extraction of low-grade ore. There is probably in the Imperial, Alpha, and Exchequer a large amount of ore of about the same quality as that which the Crown Point, Yellow Jacket, Belcher, and Kentuck folks have been mining.

NEW MEXICO.

DONA ANA COUNTY.

At the annual meeting, held at Lake Valley recently, the following gentlemen were elected directors of the Sierra Grande, the same being chosen for the Sierra Bella and Sierra Apache: Edward D. Cope, Ellis H. Yarnall, R. Pearsall Smith, Stuart Wood, Robert C. Canby, David Bransoul, Charles H. Helman, G. G. Posey, F. M. Endlich. Messrs. Cope and Yarnall are the only members of the old board who hold over. The bulk of the proxies were held by a man named Bacon, who had been sent out by the Philadelphia stockholders. An impression prevails in this vicinity, says the Silver City *Southwest Sentinel*, that the Sierra properties can be made to pay a handsome interest upon the investment, even at the present high capitalization, and it is hoped that the new management will take the mines in hand and honestly strive to show what the ore contains.

SANTA FE COUNTY.

BONANZA No. 8.—Work will be resumed at this mine.

CASH ENTRY.—Since the property was purchased for $40,000 by the present owners, it has been worked in a straight and regular way. In connection with this mine, are a large number of prospects. The mine is developed by two shafts—No. 1, 160 feet deep; and No. 2, 140 feet deep. At 130 feet, they are connected by a level of 150, which is extended south beyond No. 2 for 25 feet. At this depth, there are two veins which form a junction at shaft No. 2. At the junction, the ore-body is from 18 inches to ten feet in width. The larger body averages at this time about $10 silver and 30 per cent lead. The other vein, as shown in shaft No. 1 and the 130 foot level, is about 17 inches in width, while the pay-streak is from 2 to 10 inches in width. In the smaller vein, the ore is likewise principally galena, which runs about $50 silver per ton and 45 or 50 per cent lead. The mine is well timbered, has good machinery, and about 1000 tons of ore on the dump.

DAVENPORT.—It appears that the question of a water supply has been solved by this company. An artesian well, sunk at nearly the highest point where placer gravel is found, struck an immense body of water at a depth of a little more than five hundred feet. The workmen are now piping or lining the well, and in a few days the water will be pumped upon the placer ground, when actual operations will be commenced.

GALISTED MINING AND REDUCTION COMPANY.—The company has a three years' lease, with the privilege to purchase, upon the Gold Hope mine. It has begun work with the view of thoroughly developing this property.

MARSHALL BONANZA.—Continuous development-work with the view to production will soon be commenced upon the property.

ST. LOUIS & NEW MEXICO.—It is reported that this company owns 800 acres of placer ground on Tuerto Gulch, two miles and a half below Golden. It has just received a car-load of machinery, and begun active work.

OHIO.

A dispatch to the New York *World* states that the tunnel for lubricating oil is about to be driven at Mecca, under the management of a company organized in New York, with Silas B. Dutcher as president. The oil is found in an area fifteen miles in length by five miles wide. It is estimated that 500,000 barrels have been taken out by pumping wells at an average of forty feet, which would represent, at its present value of $20 per barrel, $10,000,000. It has been demonstrated that a tunnel about six feet by three feet will pay to cut through a stratum of shale that forms the division between two layers of sandstone. The company has two square miles of territory in the heart of the best developed region, and should the yield be but one pint per running foot per day, it would pay 33⅓ per cent on the capital stock of $1,000,000. The tunnel will be four miles long.

UTAH.

BEAVER COUNTY.

It is understood, says the Salt Lake *Tribune*, that the Utah Central Railroad will extend a switch out six miles toward the mines from Milford, where the upward slope begins. The ore can be delivered at this point for 60 cents a ton. There is a strong desire among the large ore-producers in this region to see a second railroad penetrate the country, since every body is convinced that smelting at Sandy is much cheaper (40 per cent, it is said) than down here, the difference being mainly in cost of labor and fuel. If really fair rates for transportation of ores could be depended on, there would never be any more smelting in this southern country.

JUAB COUNTY.

MAMMOTH.—Reports state that a suit has been instituted against the company for the recovery of sums aggregating $50,000.

MILLARD COUNTY.

RED CLOUD.—This company has been organized with a capital stock of $1,000,000. The properties belonging to the company are the Chief of the West and Last Chance, in Antelope Mining District. Salt Lake City will be the chief place of business.

PI UTE COUNTY.

BULLION CAÑON COMPANY.—This mill, at Marysville, has been undergoing an overhauling, and has been placed in good condition for working ores. The mill is operated by water-power. The latest improvement was the addition of Frue vanners to make the concentration more perfect, and now the loss of metal is very small. A lot of ore from the Pluto mine has lately been milled, saving all the assay value except about $1 per ton. Since the improvements, the mill ran a few days, and produced a bar of bullion weighing 800 ounces, which was 931 fine in silver, and contained sixteen ounces of gold. This company also owns the Pluto mine. It expects to do custom work, and to operate all winter, both at the mill and mine.

CLYDE.—The mine is developing by a tunnel now in 932 feet, and driving to cut the vein at depth of 500 feet below the surface. To do this, the tunnel will have to run 150 feet farther.

SALT LAKE COUNTY.

A number of gentlemen interested in the mining industry of Utah have organized the Salt Lake Mining Institute, the purpose of which is to report upon the prospects of mining and of business in general; to develop mines; and to sell the properties at a reasonable price to capital that will make vigorous and extensive developments.

SUMMIT COUNTY.

EMPIRE.—It is stated that the claims of the employés of this company against the property have nearly all been bought in, and it is probable its affairs will all be settled soon.

ONTARIO.—The drain tunnel, says the Salt Lake *Tribune*, tapping the mine on the 600 level, at shaft No. 3, is 5763 feet long, from its mouth to the shaft; it is 5 feet by 7 in the clear, exclusive of lumber flume on the floor, 18 inches deep by three feet wide, in which the water is running nine inches deep like a mill-race, the grade being half an inch to the rod, or 13·4 feet per mile. This tunnel cost between $25 and $30 a foot. There are two compound 17-inch plunger steam-pumps on the 800 level, lifting 2700 gallons a minute to the tunnel, and another similar pump, 14-inch, on the 700 level. The cross-drift from shaft No. 2 on the 600 level is about 175 feet long to the vein. Thence this level is opened 850 feet east. Shaft No. 3 is farther from the vein, so that the cross-drift from it to the vein, which is really an extension southward of the drain tunnel, cuts the vein 426 feet south of the shaft, and 330 feet west of any other work on the vein. They drove the 600 level west from the No. 2 cross-drift as far as they could for the water, and then bore off northwest into the hanging country, and took the shortest cut to shaft No. 3. Through this, the water lifted from below runs to the drain tunnel, a distance of some 1400 feet. It is 1150 feet on the course of the vein from shaft No. 2 to shaft No. 3, or between the cross-drifts from the shafts. This, with the 850 feet east, makes the 600 level 2000 feet long from the east face to the cross-drift from shaft No. 3. At the latter point, the vein is 10 feet thick, with one foot of about 100-ounce ore on the hanging-wall, and 1½ feet on the foot-wall. Westward of this point, the company, or some of the principal owners in it, have a block of ground 3000 feet square, through which it is certain the Ontario vein continues, and which will be opened in due time, and contribute its share to the irrigating supply of Summit County, all of which above the drain tunnel will, of course, pass off without expense. All along the surface of this new ground, the vein has been traced; and although it seems to be for the most part pinched, yet it bears the characteristic ore that has made the Ontario output of $14,000,000 above the 600 level. The entire property, it will be seen, is about one mile long. The great shaft, No. 3, is now nearing the 800 level. From the 600 level down to that station, a double 20-inch pump column is to be put in, through which a double Cornish pump, worked by the enormous engine on the surface, will send up 3000 gallons of water per minute if necessary. The shaft will be sunk to the 1000-foot level; the double 20-inch column of the Cornish pump will be extended down there. Thus it is believed that the water trouble, which for a year or two has taxed the resources of the company, has been got under control, at least for two or three years.

WASHINGTON COUNTY—SILVER REEF.

STORMONT.—During August and September, the main incline was sunk 125 feet to the 6th level, most of the distance being in ore. Under date of October 2d, the superintendent reports: Progress in 6th level has been somewhat delayed by cutting station, now completed. The south drift has been advanced nine feet, and continues to show a very good vein of ore. The probabilities are, that there is a chute of pay-ore from the 5th level, but its extent can only be told as we push the level ahead.

FINANCIAL.

Gold and Silver Stocks.

NEW YORK, Friday Evening, Oct. 12.

The number of shares dealt in at the Mining Exchange foots up a large total, but the business done was confined to a few low-priced fancy stocks. Harlem, which was raided last week, was again very largely dealt in and its price was stronger; but it was simply manipulation. Eastern Oregon, Decatur, Sutro Tunnel, Robinson, and Amie are the other stocks which were very largely dealt in, and which, in fact, comprise the whole business done in the market. In every one of these stocks, the prices did not materially change, but were generally steady. We give a full summary of the market below. The total number of shares sold aggregates 193,710 shares, as against 188,363 last week.

The Comstock shares have been very quiet, at steady prices. California was irregular, selling from 11@18@16c., with a small business. Consolidated Virginia was quiet and steady, selling from 43@50@47c. Sierra Nevada was also steady, selling from $4@$4.25. Union Consolidated was very moderately dealt in at steady prices, selling from $4.05@$4. Mexican sold from $2.20@$2.25 under small transactions. Sutro Tunnel was active and steady at 18c.

The Leadville stocks were moderately dealt in at steady prices. Amie was quite active at steady prices; it sold from 13@12c. Chrysolite was fairly active at irregular prices; it sold from $1.20@$1.10. Dunkin, with a small business, sold at 25c Breece records a small business at 16@18c. Iron Silver was moderately dealt in at steady prices, selling from $2.95@$3. Leadville sold at 43c. Little Chief was steady, with a small business, selling from 53@60c. Little Pittsburg was quiet and steady at 63@65c. Climax sold from 11@12c., under a small business.

The Bodie stocks were very quiet, and were steady. Bodie Consolidated sold from 50@55c., with small transactions. Standard was quiet and steady at $5.75@$6. Bulwer was but moderately dealt in at steady prices, selling from 52@50c. North Standard was quiet and strong, selling from 10@25@20c.

The Tuscarora stocks were moderately dealt in at stronger prices. Grand Prize was fairly dealt in and was strong, selling from 25@59@55c. Belle Isle was quiet and steady at 30@33c. Navajo was at one time quite strong, but declined toward the close; it sold from $2.65@$3.50@$3 under a small business. North Belle Isle was quiet and steady at 45@50c. Elko Consolidated was quite weak, under a small business, selling from 7@2c.

In the miscellaneous list, Alice was a little weak, under a moderate business, declining from $2.85@$2.65. Horn-Silver was moderately dealt in at steady prices, selling from $7.25@$7. Hukill was quiet and steady at 5@7c. Northern Belle records a small business at very irregular prices; it sold from $5.63@$4.85@$5.50@$5. Robinson Consolidated was quite active and was irregular; it sold from 39@34@40@37c. Sierra Grande was moderately dealt in at steady prices, selling from $1@$1.05.

Barcelona was quiet and a little weak, selling from 32@28c. Central Arizona was steady at 21@25c. under a small business. Decatur was very actively dealt in at steady prices; it sold at 4c. throughout. Eastern Oregon was also very active, and was also steady; it sold from 40@48@47c. Harlem recovered from its weak prices of last week, and was stronger under a very active business; it sold from 76@87@86c. Sonora Consolidated was almost neglected, and was steady, selling from 25@24c.

The annual meeting of the stockholders of the Amie Consolidated Mining Company was held on Tuesday last at No. 40 Broadway, this city, at which there was a good attendance. There were 402,490 shares of stock represented out of a total of 500,000. The chief object of the meeting was the election of a board of directors for the ensuing year; and, as there was considerable opposition to the present management, it proved quite interesting. Mr. Thomas G. Roebuck, of Newark, led the opposing element; but he and his friends could muster but 169,410 proxies, while the management voted on 233,080, and thus succeeded in electing the following directors: A. W. Gill, Robert Sewell, L. V. De Forrest, L. D. Roundebush, George P. Sheldon, George H. Morrison, and J. S. Lockwood. The financial statement of the company for the year ended October 5th shows that the receipts were $53,828.53; disbursements (including a dividend of $25,000 and $414.40 lost by the failure of the Bank of Leadville), $44,864.69; cash on hand, $8963.64. The superintendent, who was at the meeting, stated that he had received a dispatch from the mine that No. 5 shaft was looking very well.

It is reported that the Ontario will soon resume dividends. It has probably accumulated fully $250,000 in its treasury after paying for the coal mines and railroad.

On the Green Mountain, the following is reported from a good source: The vein has been cut at about the calculated distance. Work is going forward on the vein at the rate of 200 feet or more a month, seven and a half feet a day, with power-drills. The vein is extremely well defined; the quartz is soft and friable, and breaks into small fragments. It contains some gold, but not enough as yet to pay. There are some 500 feet to run before the Blake chute will be reached. The mills on the hill are stopped, all the stamping now being done at the 60-stamp mill. The sixth level will be extended back along the vein as far as the supposed Gregg chute or beyond. This chute is so known from the fact that it was opened by Mr. Gregg, who is now the acting superintendent of the Homestake and adjoining claims in the Black Hills.

The new management of the Sierra Grande Mining Company, under the presidency of Professor Cope, in the announcement of dividend No. 7, presents the following approximate preliminary statement, pending a detailed financial report now in preparation:

Cash in bank and at mint	$130,500
Cash—in hands of general manager at Lake Valley; receivable from ore shipped to Pueblo during September; and from other sources, partly estimated	98,500
	$229,000
Deduct dividend No. 7, payable October 3d, 1883	100,000
Reserve of cash assets, receivable by October 31st	$129,000

The circular continues as follows:

"Reductions in the current expenses of about three thousand dollars per month have been recently inaugurated, and work which has proved unproductive has been stopped. A part of the resources of the past few months has been derived from the tailings of the hurried mill work of last winter. These are now exhausted, and we shall henceforth depend on the fresh product of the mines. The output of ore is indicated by our manager as satisfactory in high-grade ore, and he reports that there are no present indications of a decrease in quantity or quality. The low-grade ore is found in large quantities and is of value. There appears to be an economy in shipping high-grade ore to a smelter in Pueblo, and in working the low grades in our own mill. But this problem is not yet fully worked out. A diamond rock-drill has just been put into operation which will save much expense in sinking shafts for discovery of ore-beds. It is also proposed to purchase concentrators for utilizing the lowest grade of ores and tailings. It is expected that the railroad will be soon extended from Nutt station to Lake Valley."

The action of Ralph D. Perkins and other stockholders against Charles Dennis, J. Warren Brown, and others, and "the Dunderberg Mining Company," which was begun in the Supreme Court of the State, has been transferred to the United States Circuit Court. The corporation was organized in May, 1879, under the laws of the State of New York, with a capital stock of $1,500,000, divided into 150,000 shares of $10 each. It is alleged that soon after the organization the defendants entered into a pretended agreement with J. Warren Brown, the owner, in trust for himself and others, of certain mining claims and property situated in Clear Creek County, Colorado, to issue to him and his associates as full-paid stock 150,000 shares for the pretended consideration of the conveyance of the mining claims and property. It is alleged that the mining property was not worth $1,500,000 nor more than $242,000, which was the sum actually paid to the several owners of it. The plaintiff prays that the defendants may be ordered to account concerning the gains and profits received by each of them from the sale of said stock, and that the value of the property in question be determined by the court.

DIVIDENDS.

The Castle Creek Gold Mining Company, of Idaho, has declared a dividend (No. 17) of three per cent, payable October 16th.

The Copper Queen Mining Company, of Arizona, has declared a quarterly dividend of $125,000, payable October 16th.

The Holyoke Mining Company, of Idaho, has declared a dividend (No. 13) of two per cent, payable October 18th.

The Juniper Gold Mining Company, of Idaho, has declared a dividend (No. 1) of two per cent, payable October 20th.

The Mount Diablo Mining Company, of Nevada, has declared its third consecutive monthly dividend of twenty-five cents per share.

The Oro Grande Mining Company, of California, has declared a dividend (No. 3) of $16.000.

PIPE LINE CERTIFICATES.

Watson & Gibson, petroleum brokers, No. 49 Broadway, report as follows for the week:

The market for the past week has been a declining one. Friday, October 5th, it opened at $1.13¾, sold down to $1.12⅝, closing dull at $1.13⅛. There was considerable covering of short accounts at about these figures, and the market was devoid of such strength as comes from short buying. Saturday, the market was stationary at about $1.13¼. Monday, the market exhibited weakness. The immediate cause of this weakness was the announcement that Howe No. 10 had come in over Sunday, and had made 150 barrels the first hour. It had declined by Monday morning, but the evidence was unmistakable that the Balltown production was increasing to an extent that alarmed the bulls and made a decline seem probable. Tuesday, the market dropped down to $1.10⅛, recovering at the close to $1.12 in anticipation of the Pipe Line report which was to appear the next day, and the agreement among prominent Balltown and Cooper tract producers to suspend the starting of any new wells until next spring. This bull feeling was very unsubstantial; but early Wednesday morning, the market rose to $1.13. It soon began to drop, however, and did not stop till it reached $1.09¼. Thursday, the market declined to $1.07⅛, rallying at the close to $1.09⅝. This (Friday) noon, the market, after having declined to $1.08⅝, rallied to $1.10¼, but there is nothing in the situation at the present moment to justify high prices for oil.

The following table gives the quotations and sales at the New York Mining Stock and National Petroleum Exchange:

	Opening.	Highest.	Lowest.	Closing.	Sales.
Oct. 6	$1.13¼	$1.13¾	$1.13	$1.13⅛	2,260,000
8	1.12⅝	1.12⅝	1.11⅝	1.11½	4,373,000
9	1.11¼	1.12¼	1.10½	1.12⅛	3,347,000
10	1 12	1.13	1.09¼	1 0⅝	5,243,000
11	1.09⅛	1.09⅝	1.07⅞	1.09½	4,206,000
12	1.09⅜	1.10¾	1.08⅝	1.10⅝	4,384,000
Total sales					23,813,000

Copper and Silver Stocks.

Reported by C. H. Smith, 15 Congress street, Boston, Stock Broker and Member of the Boston Mining and Stock Exchanges.

BOSTON, October 11.

There is no improvement to note this week in the market for mining stocks, which continues to rule dull, with prices inclined to a lower level. This is not because of any change in the price of ingot copper to warrant a decline, but is one simply of supply and demand. The orders to purchase stocks from *bona-fide* investors are few, and as there are two sellers to one buyer, some have to be left out in the cold or submit to lower prices in order to effect sales. As an instance, take Quincy, which last week was strong at $54 on good buying orders, this week has declined to $51, for no other reason that we can learn than an absence of orders to buy, there being no disposition to speculate in the stock. Calumet & Hecla has ruled steady and firm at $245. The usual quarterly dividend of $5 per share is announced. Franklin continues firm at the advance of last week, with sales at $12½@$12¾; while Pewabic, on the expectation of another assessment, has declined from $2½@$1½, and closed at $1¼ only bid for it. Osceola sold at $19@$19½. The rest of the list is entirely neglected.

In silver stocks, the market is duller than ever. With the exception of Silver Islet, there is really nothing doing. Silver Islet advanced from $3@$3½ on the strength of the strike alluded to last week; but he public generally do not take kindly to these reports, and are cautious about making investments in this class of mines, especially when assessments are the regular rule rather than the exception. Bonanza sold at $1¾, same as last week (100 shares only). Sullivan at 87½c., and at the Mining Board at 85c., seller 30. Bowman Silver, 12@18c. Harshaw, at 50c.

3 P.M.—The market this afternoon was without any special feature. Pewabic sold at $1¼. Silver Islet at $3. Quincy, $51@$50¾. Franklin, $12½ bid, $13 asked. Osceola, $19 bid, $21 asked. Atlantic, $10 bid. Pewabic, $1¼ bid, $1½ asked. Bonanza, $1½ bid, $1¾ asked.

BULLION MARKET.

NEW YORK, Friday Evening, Oct. 12.

The market has been pretty steady the past week until to-day, when a decline of 1/16d. in London, and the equivalent of ⅛ per ounce in sterling exchange here, reduces our figures one quarter of a cent per ounce, as quoted in annexed table:

DATE.	London. Pence.	N. Y. Cents.	DATE.	London. Pence.	N. Y. Cents.
Oct. 6	50 15-16	110¾	Oct. 10	50 15-16	110¾
8	50 15-16	110¾	11	50 15-16	110¾
9	50 15-16	110¾	12	50⅞	110½

The Assay of Japanese Coins.—Dr. Lawyer, the assay officer of the Mint Bureau, has just completed his test of the pyx coins sent from the Imperial Mint at Japan, and has made his report to the Director of the Mint. The results of the test correspond so closely with the results of that made at the Japanese Mint as to be thought remarkable.

BULLION PRODUCTION FOR 1883.

We give below a statement showing the latest bullion shipments. These are officially obtained from the companies, where that is possible; and where official statements can not be procured, we take the latest shipments published in those papers nearest to the mines reported. The table gives the amount shipped for the week up to the date given, as well as the aggregate shipments to such date from the first of January, 1883.

The shipments of silver bullion are valued at $1.29·29 per ounce troy; gold at the standard $20.67 per ounce troy. The actual value of the silver in the following table is therefore subject to a discount, depending on the market price of silver. If the price of silver be counted at $1.11 an ounce, which has for some months been about its average value, the following figures, where they relate to silver bullion, should be diminished by about 14½ per cent, to arrive at actual value.

MINES.	States.	Month of August.	Year from Jan. 1st, 1883.

Cheap Nickel for Coinage.—Col. A. Loudon Snowden, Superintendent of the United States Mint at Philadelphia, received at noon, October 3d, bids for 20,000 pounds of metal to be used in minor coinage. Joseph Wharton was the only bidder, but his figure, ninety-one cents per pound, is the lowest at which the government has ever been able to get the metal.

Bullion Receipts at New York.—The bullion received from the mines at the various offices in this city during the week ended October 12th, as compiled from various sources, amounted to $296,000, as against $160,000, reported for the previous week. The receipts from January 1st, 1883, to date are $8,945,047.

Exports and Imports of Gold and Silver at New York.

Exports.

Week ended October 6th	$339,900
Corresponding week last year	58,200
Since January 1st, 1883	11,378,076
Corresponding period last year	44,301,795

Imports.

Week ended October 6th	$674,790
Corresponding week last year	261,517
Since January 1st, 1883	12,906,220
Corresponding period last year	3,368,985

Foreign Bank Statements.—The Governors of the Bank of England, at their regular weekly meeting, made no change in the bank's minimum rate for discount, and it remains at 3 per cent. During the week, the bank lost £492,000 bullion, and the proportion of its reserve to its liabilities was reduced from 43 15-16 to 42¼ per cent, against 32½ per cent at this date last year.

The Coinage of Silver.—From an official statement made by Mr. Burchard, Director of the Mint, it appears that the silver on hand on July 1st, 1878, and purchased since then, is 123,447,480 ounces, of which 119,206,224 ounces have been used in the coinage of silver dollars and some subsidiary silver coin, 304,375 ounces have been wasted by the operative officers of the mints and sold in sweepings, leaving a balance on hand July 1st, 1883, of 3,936,880 ounces. This remainder has been weighed and verified by officers of the Treasury Department.

The profits on the coinage of this silver, including the repayments by the Adams Express Company, amount to $17,342,113, of which sum $15,581,718 have been deposited in the Treasury of the United States, $358,399 have been paid for shipping silver dollars, $51,925 for loss on sweepings sold, $71,429 for wastages, and $48 for loss on recoinage, leaving a balance in the coinage mints on June 30th, 1883, of $1,278,596, all of which has since that date been covered into the Treasury.

METALS.

NEW YORK, Friday Evening, Oct. 12.

Copper.—Sales for the week have been confined to a couple of hundred thousand pounds Lake Superior at 15¼c., which is the asking price at the close, 15⅛c. being bid. Other brands sell to a moderate extent at from 14⅜@14¾c. As the contracts for Lake copper with manufacturers expire this month, the question arises whether a new pool is to be made. It will be made if the manufacturers see any advantage in the conditions offered them; if not, they may as well fill their current wants at ruling prices from hand to mouth—and this seems to be the feeling. The Chili Bar speculation in London after all does not seem to work satisfactorily, good ordinary brands of Bars being down to £61 7s. 6d. (to-day's cable), and New Selected to £68.

Tin.—The large shipments from the Straits this way, and from Australia to London, combined with dullness in the metal trade both in Europe and here, have caused a downward tendency on both sides for the moment so far as large lines of Straits are concerned, while, in a jobbing way, prices are tolerably well sustained. Thus, we quote large lots on the spot 21c., and smaller parcels 21⅛@21¼c. London has meanwhile given way to £93 15s. with Straits Tin.

Lead.—Since our last report, some 600 tons of Common lead have been forced on the market and have gone at 4·20c., which is the closing figure on a firm market, Refined barely being worth 4·25c. The general tendency is a weak one just now, and will probably remain so unless a brisker demand for consumption should soon manifest itself, in which respect both September and so far October have been a disappointment. Chief consumers here are meanwhile still sufficiently stocked to be able to bide their time a couple of weeks longer, if need be. Much will depend, as regards prices in the near future, on the course the one or the other of the big holders out West may choose to adopt with what he has still on hand. London cables English Pig £12 7s. 6d. @£12 10s., steady.

From Chicago, Messrs. Everett & Post send the following dispatch:

Our market has declined slowly since our last report. The demand is only moderate, and there is but very little doing. Buyers are holding off, expecting a further decline, and are purchasing only for immediate wants. Sales for the week have been 800 tons Common and Refined at 4c.

Spelter.—The market for Common Domestic spelter is about as listless as it has been for months past, at 4½c., while Silesian is worth 5½c., nominally. Under date of the 28th ult., Messrs. H. R. Merton & Co., London, write:

A large business has been done at improving prices, £15 12s. 6d. for special, and £15 7s. 6d. for ordinary brands having been paid. Makers abroad will only sell moderately, as they believe in higher prices.

There is also a large demand for sheet-zinc, prices

Digitized by Google

of which are also moving upward. At the fortnightly sheet-zinc sale, 50 tons were sold at £18, which is an advance on the last sale price.

Cable advices state that the market continues steady at the improvement.

Antimony has been quite dull at 9⅛c. Hallett's, and 10¼c. Cookson's.

IRON MARKET REVIEW.

New York, Friday Evening, Oct. 12.

American Pig.—The Metal Exchange has the following returns from ninety-five furnaces up to October 1st:

Grade.	Stocks. Sept. 1.	Stocks. Oct. 1.	Production. Sept.	Production. Oct.
No. 1	18,617	16,663	10,011	10,398
No. 2	14,102	12,585	4,887	5,951
Bess., Forge, and lower grades	51,535	48,194	31,800	33,749
Grade not specified	32,170	31,013	14,019	14,915
Total	116,424	108,473	61,617	65,013

There is nothing new to report in this trade. Business remains in the same apathetic state that it has been for some time past, and while a fair consumption is going on, there are but very few buyers in the market. Some of the furnace companies threaten to cease production, and already there are some furnaces blowing out along the Lehigh, Schuylkill, and Susquehanna rivers. This would be a wise action at this time, and would help the market considerably, as prices would thus be forced to a higher figure than at present. We quote No. 1 Foundry at $21@$22; No. 2 at $19@$20; and Gray Forge at $19.

At the Exchange, the following transactions were recorded:

Saturday, 1600 tons of pig. Monday, 100 tons, No. 1, January, $20.50. Tuesday, 100 tons, No. 1, May, $21.

Scotch Pig.—This trade is very quiet. Nothing new has been done that we hear of. Imports are gradually diminishing, and prices abroad remain very firm, owing to labor troubles and cost of coal.

We quote ex ship and to arrive: Coltness, $23.25; Langloan, $23.25; Summerlee, $22.75@$23; Eglinton, $21; Glengarnock, $22@$22.50; Dallmellington, $21.

At the Exchange the following cable quotations were received to-day: Coltness, 57s. 6d.; Langloan, 57s.; Summerlee, 56s.; Gartsherrie, 54s. 6d.; Glengarnock, at Ardrossan, 54s.; and Eglinton, at Ardrossan, 48s. Warrants at the Exchange to-day were 46s. 8d.

Rails.—There has been a little better demand for steel rails, and we hear of orders for some 20,000 tons at Pennsylvania mills at $37, for delivery in 1884. Prices, however, remain unchanged, and we quote, as last week, $37@$37.50, at mill.

Old Rails.—Nothing is doing in this trade. Old rails are scarce, and some spot lots are held firmly. We quote $22.50@$23 for Ts.

Scrap.—Scrap continues dull at $23.75 ex ship.

Philadelphia. October 11.

The pig-iron market has not recovered in any respect from the unfavorable condition in which it was reported last week. The consumptive requirements seem to have fallen off, but actual consumption has not. Stocks in makers' yards are lighter than usual, and a number of large consumers have about reached the end of their summer contracts. Were it not for the present fluctuations in prices, large contracts would be placed at once by these parties; but they have concluded to wait until prices have reached bottom limits, or until conditions are more favorable. The usual quotations are $21@$22 for No. 1 Foundry, though a number of small sales have been heard of at $20@$20.50 for what is called No. 1. No. 2 continues in greater abundance than No. 1, and ranges in price from $19@$20, with average sales at or near $19. A few brokers have been endeavoring to close out large lots at furnace banks. A few large sales have been made, but the bulk of business is trifling. Gray Forge has not weakened, except in the case of a few inferior irons, which were placed at $17 at furnace.

Foreign Irons.—Nominal quotations given for Bessemer, $29.50@$31. Brokers, who had inquiries for large blocks some time ago, are seeking buyers at the former figure; but no large transactions, and but few small ones, have been heard of. It is expected that Bessemer will decline, although no reason has been given for this belief.

Blooms.—At the bloomaries, there is a fair degree of activity, and orders run a month ahead for charcoal and anthracite at old quotations. Unusual concessions have been heard of in both qualities; but it is uncertain whether the figures at which business was done will be permanent.

Muck Bars.—One or two sales have been heard of at $35, and some inferior irons have sold as low as $33. Standard are firm at $34 for small lots; in large lots, these figures are shaded.

Manufactured Iron.—It is said to-day that some manufacturers will reduce to single turn unless demand should improve. The feeling in the finished iron trade is far from satisfactory. The depression is greater than at any former time. At the best prices obtained, there is very little in iron; and with the fluctuating demand and weak prices, the outlook is very discouraging. Quotations are nominally 2·15c., but business, especially in the country mills, is done away below this figure. Some few transactions in common iron have been closed at 1·80c. Good makes of common are held at 1·90@2c.

Plate and Tank Iron.—The situation in plate and tank iron is more satisfactory in consequence of the heavy demand and the large orders in hand for delivery during October and November. A decline is looked for on account of the weakness in the other departments. Some requirements are held back in view of this fact. Quotations are 2·50c. for Plate, with Shell and Flange 3c. and 4c., in large lots. Locomotive requirements are fair; but lots are bought for pressing requirements only, and works are carrying but little stock.

Structural Iron.—No heavy transactions can be reported, although there are specifications in hand which will probably be placed this or next week. Prices are unchanged.

Steel Rails.—Steel rails are quoted at $37@$37.50; but the impression prevails that the offers of large buyers will yet be accepted, though no actual business has been closed.

Old Rails.—There are a number of inquiries in hand, some of which have been floating around for several weeks. Bridge rails are offered at $24.50; Double Heads, $26; Tees, $23.25. Material could be sold at about 50 cents below these quotations. Buyers of small lots will give 25 cents less than holders ask.

Nails.—Nails have dropped to $2.85, in consequence of the offerings of the Danville and other new mills. Trade price, $2.90. Jobbing price, $3.

Scrap.—A fair amount of scrap was carted out of yards this week at $25 for best, and from that down to $20 for inferior.

Pittsburg. October 11.

There are no signs of improvement in the Western Pennsylvania iron trade, notwithstanding the efforts of outside parties to unload stocks at concessions from rates heretofore asked. Among sales reported are 250 tons of Gray Forge at $18; 1500 tons of Bessemer at $20.50; sales of Foundry at $18.50@$19. Muck Bars are selling at $33. Manufactured iron, 1·80c. Nails, $2.70. Wrought Pipe, 75 per cent off list. Tubes, 60 per cent off. Inquiries for Old Rails are in hand at $24.50@$25 asked. Winter deliveries of Steel Rails, $37. Merchant Steel, 11@12c. for Refined Cast; Crucible machinery, 6@7c. Crop Ends, $23.50@$24.

Graff, Bennett & Co.'s mills at Millvale have been shut down for want of gas. Bridge and locomotive-works are crowded with orders.

COAL TRADE REVIEW.

New York, Friday Evening, Oct. 12.

Anthracite.

The situation has not materially changed from last week, and there is absolutely nothing new to report. The trade is demoralized, and can not recover until there is the most decisive evidence of co-operation among the companies. As they now stand, the Delaware & Hudson, the Lehigh Valley, and the Lehigh & Wilkes-Barre probably unite in recommending an early stoppage. The roads will be simply blocked, if the present state of affairs continues for a week. The Delaware, Lackawanna & Western, it is presumed, is indifferent, while the Philadelphia & Reading and the Pennsylvania Coal Company want to continue full-time, the latter because in about thirty days stocking for its upper river trade will cease, so that it is now exceptionally busy.

President Gowen, of the Reading Road, was in this city last Tuesday, but no consultation of the head officials was held; and no agreement was entered into.

A telegram from Philadelphia states that the Girard estate has leased its mines in Schuylkill and Columbus counties, Pa., to the Philadelphia & Reading Coal and Iron Company, the Lehigh Valley Coal Company, the Thomas Coal Company, the William Penn Coal Company, and Myers, McCreery & Co., for fifteen years from January 1st, 1884, on a royalty of forty cents per ton the first year, and increasing annually one cent per ton during the continuance of the leases. The collieries were previously leased for fifteen years to the same tenant at 25 cents per ton and 1 cent additional each year, the rate being 39 cents for this year. These collieries produced last year 1,500,000 tons of coal.

Bituminous.

The bituminous trade continues very dull, and there are but few small orders reported. Vessels, which were driven in larger numbers into Boston harbor by the late storm, have been generally distributed to their different shipping points, and are consequently in better supply than of late. Low prices still prevail.

Horsford's Acid Phosphate

A Good Thing.

Dr. Adam Miller, Chicago, Ill., says: "I have recommended Horsford's Acid Phosphate to my patients, and have received very favorable reports. It is one of the very few really valuable preparations now offered to the afflicted. In a practice of thirty-five years I have found a few good things, and this is one of them."

MAPS.

ARIZONA AND NEW MEXICO.—This map shows all the Township Surveys, Private Land Claims, Post-Offices, and Settlements. It also exhibits the Explorations of other Government and Private Expeditions, including the facts developed by the Surveys for the Routes of Projected Railroads, etc., 1881. Scale, one inch to thirty-three miles. Colored, 24×17 inches. Pocket form, $1.

COLORADO.—Topographical and Township Map of the State. Compiled from U. S Government Surveys and other authentic sources, by Louis Nell, Civil Engineer. By means of symbols, the following mass of facts is graphically shown: Railroads in operation; Railroads chartered or in progress; Wagon-roads; Wagon-roads proposed; Trails; Drainage dry during the greater part of the season; County-seats; Post-offices; Villages; Townships subdivided; Townships surveyed in outlines; Contour-lines, with vertical intervals of 1000 feet; Altitudes in feet above sea level, by barometer observations and by spirit-levels; Private grants; Military reservations; Indian reservations ceded to the U. S. Government; Arable land, with irrigation. Tables of Areas of Counties; Astronomical Positions; Arable Land. Scale, 1 inch: 10·5 miles. Size, 31×40 inches. Pocket form. $1.50 on thick paper.

IDAHO.—The Wood River Region of Central Idaho, giving the first correct Geography of that recently explored and remarkable Belt of Discoveries of Gold and Silver Mines on the tributary streams of the WOOD and LITTLE WOOD Rivers, on the Upper Waters of the SALMON RIVER, among the SAWTOOTH MOUNTAINS, and on the Forks of the BOISE RIVER; embracing the Mount Estes and Custer Mines on the north and the Oregon Short Line Railroad on the south. Prepared by Frank J. Scott. Scale, 6 miles to the inch. Size, 15 x 26 inches. In paper pocket. Price, $1.

MEXICO.—Map of Mexico. Showing Railroads, Broad Gauge and Narrow-Gauge, Constructed; and Railroads, Broad-Gauge and Narrow-Gauge, Proposed. This very large and finely-engraved Map, constructed originally by the government for official purposes, contains all the information obtainable by it, and shows minutely the towns and villages of the entire country. Scale: 26·6 Mexican Leagues to the degree, and 69·16 English Miles to the degree; also, Kilometrical Scale. 1881. Size, 53X41 inches. Printed in colors. Pocket form, $5.

MAP OF MINING CLAIMS ADJOINING LEADVILLE, California Mining District, Lake County, Colo. By Edward Rollandet. 1879. Mounted on muslin, $2.50. In cloth-bound covers, $2.

MINING MAP OF UTAH.—Showing the location of the Mining Districts, over an extent of territory 150 miles from North to South. Compiled from U. S. Government Surveys and other authentic sources. Scale, one inch to four miles. Colored. 1879. Pocket form. $1.50.

NEW SECTIONAL AND MINERAL MAP OF UTAH.—Pocket form. Compiled from the latest U. S. Government Surveys and other authentic sources, exhibiting the Sections, Fractional Sections, Counties, Cities, Towns, Settlements, MINING DISTRICTS, Railroads, and other internal improvements. Scale, one inch to eight miles. Colored, 1878. $3.50.

POCKET MINING ATLAS OF THE MINES OF THE UNITED STATES.—Showing the Mines of NEVADA: the Comstock Lode, the Eureka, Treasure Hill, and Toscarora Districts; CALIFORNIA, including Map of the Bodie District; COLORADO, including the Leadville, Silver Cliff, San Juan, Caribou, and Central City Districts; DAKOTA, including Map of Deadwood; MONTANA, IDAHO, UTAH, ARIZONA, NEW MEXICO, LAKE SUPERIOR REGION, the SOUTHERN STATES. 1880. Printed in colors, and bound in flexible leather covers. Price, $1.

EMIL WOHLERS, a prominent German engineer, and a member of the firm of NATHAN & DREYFUS of this city, died recently in Vienna, when on a visit. He was the representative of the Friedman injector, and introduced it here.

THE Ontario Silver Mining Company has recommenced making dividends. These have now amounted to five million dollars. A splendid record and testimonial to the honesty and intelligence of the company's management.

UNDER "MINING NEWS," in our issue of September 29th, we made favorable mention of the New York Mining and Milling Company's property in Colorado. We have since received information from very reliable and well-informed sources which is very unfavorable to the enterprise. We feel it our duty to the public who may be disposed to invest in this concern to state that there is at least such a difference of opinion as to the value of these mines as should induce prudent capitalists to desire fuller information from disinterested sources as to their value before investing.

WE referred in a recent issue to the proposal made by POETSCH, in Germany, to facilitate sinking through quicksand by freezing the ground. More complete details are now available through a communication by Professor G. KOEHLER, of the Clausthal School of Mines. The enormous difficulty encountered in many important works, in mining as well as in railroad tunneling, notably on the continent, are well known to engineers, by whom quicksand is more dreaded as a source of very heavy expense and delay than the hardest and toughest rock. The Poetsch method will, we are convinced, take rank among the best means of getting through such ground; and however absurd the method may appear at first sight, it has in it the elements of considerable value under special circumstances. After he has reached the quicksand in the ordinary way, he puts down a number of holes, three feet apart in a circle, through the layers of quicksand, at such an angle that they reach into the ground through which the shaft must pass. Further, a smaller circle of holes is put down in the bottom of the shaft and one in its center. All of the holes are sunk by means of a sand-pump, being tubed as they go down. A circular distributing-pipe is suspended above the bottom of the shaft, copper tubes provided with cocks connecting with each of the holes and descending in them to their bottom. Though these copper tubes he pumps into the holes a solution of calcium and magnesium chlorides reduced at a temperature of 25 degrees Celsius below zero. The solution flows to the bottom of the holes and ascends in them in the annular space, being gathered as it reaches the top of the holes by a collecting-pipe. It took from 10 to 14 days to freeze a deposit of 12 feet of quicksand into a solid mass of ice through which sinking may go on without any danger of accidents from water.

SOMEWHAT prematurely, to say the least, some people in the lead trade are beginning to protest that mining argentiferous lead ores will soon become or now threatens to become an unprofitable business, because the prices of lead are falling. On a declining market, this cry is generally raised, and our experience has been, that the pressure of necessity creates efforts at economy which have a wonderfully scaling effect upon the cost of production. It is at a time like the present that there is a fruitful crop of estimates, which, as they come from those who would like to stay the downward tendency of prices, do injustice to the mines. As an example, we quote the following from a letter written by Messrs. J. H. ACKERMAN, metal merchants of this city, to the *Iron Age*, in which they protest against the statement that the Pueblo Smelting and Refining Company was understood to have on hand 7000 tons of lead :

"To mine 10 tons of lead ores, fully 23 tons of matter are taken out on an average. Say, to mine 23 tons of matter, at $3.45 per ton, $79.35.

10 tons of ore from 23 tons, at $7.93	$79.25
Assorting 10 tons of ore from 23 tons of rock, dirt, etc	10.00
Cartage from mines to railroad depot, from 3 to 22 miles, $2 per ton	20.00
Freight on 10 tons to smelter, say, average from 60 to 700 miles.	60.00
To smelt 10 tons ore in bullion lead, $6 per ton	60.00
Total	$229.35
As ores do not average over 15 per cent per ton of 2000 pounds, it takes 10 tons of ore to produce 3000 pounds bullion, at 4¾c.	$142.50
Average amount gold and silver in 3000 pounds bullion, at $60	90.00
Total	$232.50

"Or profit to mines of $3.22 on 10 tons of ore, if the following prices are obtained :

Price of 3000 pounds bullion lead, at $50 per ton	$75.00
Freight to New York or Newark, at $31.50 per ton	47.25
Cost of separating 3000 pounds (1½ tons), at $12 per ton	18.00
Gold and silver	90.00
Interest, two months, on outlay	2.32
Total	$232.57

Now, there is loss in smelting ores, from 2½ to 5 per cent, we have not calculated for.

3000 pounds lead at 4¾ cents	$142.50
Gold and silver	90.00
Total	$232.50

"You see there is loss. You see mining ores at $3.40, and should lead bring 4¾ cents per pound in New York, there is loss of 7 cents per ton. You can not say $3.45 is too much to mine lead. Coal companies obtain as much. These figures show why there are so many worthless mining companies—depreciation in the value of their stocks—as a good, fair mine don't pay to work, and few mines will produce 10 tons of ore out of 23 tons taken out.

If these figures were correct, the outlook for lead mining in the far West would be discouraging enough, not to speak of the Missouri mines. The latter, not having argentiferous ores, have always been looked upon as the weakest, and yet the large producers of that section can undoubtedly lay down lead in New York for 3·75 cents, and some of them for half a cent less.

It is a dangerous thing to generalize on the cost of mining of a metal like lead, whose production is scattered over so enormous an area. The conditions affecting the cost are not equal in any two localities ; and even in the same camp, they vary with every individual mine. A little more water, a crumbling roof, the existence of large areas of barren ground, a lower grade, the admixture of a small percentage of some refractory metal, or a large percentage of silica, singly or combined, may double or treble the cost of production or reduce the net returns. There is another point which must not be forgotten. When the margin of profit for a mine becomes so small as to imperil its existence, there are few managers

Digitized by Google

or boards of directors who can resist the temptation of doing less expensive dead-work, of taking risks by light timbering and of worrying along with an impaired plant of machinery. The falling off in ore supplies makes the smelters more eager to secure material, by scaling down the profits; and last, but not least, the railroads are liable to listen more attentively to complaints as to rates. In 1878 and the spring of 1879, when lead receded from 4·35 in January, 1878, to 2·87 in May and April, 1879, the statement that the mines could not live was repeated over and over again, and yet the only effect of low prices was to check the extraordinarily rapid pace at which the production was increasing. The following statement of the output for the period 1872 to 1882 will fully illustrate this point:

PRODUCTION OF LEAD IN THE UNITED STATES.

1872	25,880 net tons.	1878	91,060 net tons.
1873	42,540 " "	1879	92,780 " "
1874	52,080 " "	1880	97,825 " "
1875	59,640 " "	1881	117,085 " "
1876	64,070 " "	1882	132,890 " "
1877	81,900 " "		

Since then, great progress has been made. The extension of the railroad system in the West has rendered much more territory accessible, has opened out new sources of fuel supply, and has cheapened the cost of shipment to market. We have now magnificently appointed smelting-plants, under the management of skilled metallurgists. Some of them, and, to a less pronounced extent, all of them, use the lead simply as a carrier of silver. They purchase lead ores low in silver, which by themselves would not pay to work, for the sake of being able to work to advantage refractory silver ores carrying little or no lead. The desilverizing works have improved their methods and lowered the cost. All these circumstances have contributed toward lowering the cost, and making available ores of a grade which, five or six years ago. would have promptly wandered to the dumps, and better concentration has even reduced the quantity more.. What this means, every mining engineer will fully appreciate. It brings down the cost in almost every department, and reduces the vicissitudes to which every mine is liable. It more than compensates for the increased outlay of working at greater depth.

To attempt estimates of cost of mining under such circumstances is more than hazardous. We do not know upon what rests the arbitrary assumption, quoted above; that it costs $7.93 to mine per ton of 15 per cent ore. We prefer to look at the problem from a different point of view. Let it be assumed that lead is worth 4 cents per pound at New York—it brings 4½ cents now—then the final products would be $80 per ton for the lead, and say $100 for silver and gold, which is a very low average. Deducting cost of desilverizing, $12 per ton—which leaves a good profit to the refiners, as it does not cost more than $9 per ton, and some of the works can do it for considerably less—and $31.50 for freight, we have net value at the smelter, in Colorado, $136.50. Assuming the ore to carry 15 per cent of lead, it would take, say, seven tons of ore to make a ton of base bullion. With the cost of smelting at $6 per ton, a figure which must not be confounded with the smelting charges, the smelter would have to pay $42 to cover his expenses, which would leave him $94.50 to pay for seven tons of ore at the smelter. Deducting $35 for freight from Leadville, would leave a net price at sampling-works of $59.50 for seven tons of ore, or $8.50 per ton for ore running 15 per cent of lead, and allowance being made for loss of silver, twelve ounces. This would be about equivalent to the payment of twenty-five cents per unit for the lead, a very low figure, it is true, and a smelting charge of $8 per ton. On the other hand, the average of Leadville bullion runs near $130 per ton, and the ores therefore range higher in silver. Our object was merely to show how low grade an ore can be worked. According to Messrs. ACKERMAN'S showing, it would be possible to mine ore at a profit which would carry only about 9 ounces of silver, provided lead brings 4¼ cents a pound in New York, even accepting their estimate that 13 out of 23 tons of mineral hoisted from the mine would go to the dump.

How large a margin some of the largest producers have is shown by the record of the Horn-Silver last year, when it made 16,000 tons of lead, nearly one ninth of the total production. The mine produced 47,232 tons of ore, at a cost of $4.44 per ton; the smelting at Francklyn costing $14.73, and the refining at Chicago $9.05. The ore carried on an average 37·8 per cent of lead and 32·2 ounces of silver, the loss in smelting being 9·71 per cent of the lead and 2·10 per cent of the silver. The average of the grade of the base bullion produced in Utah was 93 ounces per ton, or, deducting allowance for silver to desilverizing-works (5 ounces), 88 ounces per ton, having a value of $95 per ton at New York, with silver at $1.08 per ounce. The dividends during 1882 amounted to $1,200,000, while the net receipts from the sale of lead were $1,326,664.23, thus indicating that the silver paid for nearly the entire cost of extraction, treatment, administration, and marketing. Like all others, it will of course suffer from a low price of lead, but will, with the same grade of ore and the same cost of mining go on producing uninterruptedly.

It will not be denied, of course, that low prices of lead will seriously affect a large number of mines in the West; but to state that even a small minority of them have reached the point where they must stop or make heavy drains on the resources of their stockholders, is somewhat rash. In spite of the disapproval of our Western contemporaries, we must, however, repeat our warning to all interested in the metal, that they should prepare for low prices. We are not inclined to rush at the conclusion reached by our contemporary, the *Iron Age*, that we shall not stop until the export point is reached. Even if there should be no revival of the demand, the decline will probably be gradual. An attempt to stem it by claiming that the point is nearly reached when there will be a curtailment of production does injustice to our mining enterprises in the far West.

CORRESPONDENCE.

[Communications will be noticed only when accompanied with the full name and address of the writer. Unless specially desired, only initials will be printed. We invite criticism and comment by the readers of the ENGINEERING AND MINING JOURNAL. Replies not intended for publication should be addressed to the Editor of the ENGINEERING AND MINING JOURNAL in blank, stamped, and sealed envelopes. We do not hold ourselves responsible for the opinions of our correspondents.]

Purchasers of Copper Matte.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: Will you give me the names of English companies buying copper matte, having agents in this country? Our mines are located in Old Mexico, and we are about to start our works. We desire to sell our products to English companies on account of the free tariff between Mexico and England. L. C.

YORKVILLE, ILL.

[We have heard that at least one English concern and one German works buy mattes in this country through local agents; but in the absence of direct communication with them, are not at liberty to give their names. We would, however, call the attention of our correspondent to the fact that American works are not necessarily barred out because there is a duty on copper in ore or mattes. It may be imported, converted into ingot, and re-exported under the drawback clause. The latter, it is true, has troublesome restrictions; but our correspondent owes it to our home industry to give it at least an opportunity to bid. If he will address Messrs. Pope, Cole & Co., of Baltimore, Md., or the Orford Copper and Sulphur Company, Nos. 37 and 39 Wall street, New York, he may possibly find it unnecessary to ship to Europe directly.—ED. E. AND M. J.]

THE TROY MEETING OF THE AMERICAN INSTITUTE OF MINING ENGINEERS.

After a few hours had been devoted to visits to a number of collar and cuff factories and laundries, the

THURSDAY'S MORNING SESSION

was opened with a paper by Dr. Persifor Frazer on

NEW FOSSILS RECENTLY DISCOVERED IN THE PEACH BOTTOM SLATES

in York and Adams counties, Pa. The age of the early Cambrian rocks has been the subject of considerable discussion among geologists. One class believes that the Potsdam and Calciferous, and even the Hudson River, belong to a much higher horizon than the lower Paleozoic, while others hold that all three belong below it. Professor Dr. Persifor Frazer has made an interesting study of the Peach Bottom slates, and has found in them fossils which have been submitted to Professor Hall, of Albany, for determination.

Professor Frazer then called the attention of the members to the color of an anode used in the electrolytic determination of copper. Mr. Mackintosh, who has had a wide experience in this class of work, explained that the dark film on the anode was produced by a deposit either of peroxide of manganese or of peroxide of lead.

Mr. H. M. Howe, of Boston, then read a paper on an ingenious proposal for a Systematic Nomenclature for Minerals, to which we shall have occasion to refer at greater length in the future. Professor Egleston, in discussing the paper, gave the results of his experience in teaching mineralogy during the past twenty-one years.

The session was concluded by the presentation of a note by Mr. P. Barnes, of Springfield, Ill., on the water-gas producers at the Elgin Watch Company's works. The works had been provided with a plant for illumination by means of water-gas, and the idea was natural to attempt the use of water-gas also for firing the boilers, the air-blast being heated by the waste gases. It was found that, with coal at $5 per ton, the gas would have to be furnished at as low a figure as 5 cents per 1000 cubic feet before the gaseous fuel could compete, in the point of economy, with coal. The attempt was abandoned.

THURSDAY AFTERNOON SESSION.

The last session was opened with the election of a large number of members and associates, followed by the reading of a paper by Mr. John Fulton, mining engineer of the Cambria Iron Company, Johnstown, Pa., on

THE PHYSICAL PROPERTIES OF COKE AS A FUEL FOR BLAST-FURNACE USES.

Mr. Fulton, to whom belongs the credit of having first and most thoroughly inquired into this special subject, gives the results of his observations, made as early as 1875, to investigate the causes of the lower value of a coke produced from local coals at Johnstown, as compared with fuel from the famous Connellsville region. Chemical analysis gave no cue, and he turned to physical properties distinguishing them to explain their relative values. Mr. Fulton goes over the ground traversed in recent publications in a controversy between the Connellsville *Courier* and *The Virginias*, and adds a few data confirming former researches, and on the whole his paper contains little that has not been touched upon in them. After speaking of the suggestions made in *Coal*, that the blind following of the Connellsville coking methods has ignored the character of the coal, Mr. Fulton states that the Illinois Central Iron Mining and Coal Company is using a more rapid coking, with good results, by sustaining

Digitized by Google

the heat in its Thomas ovens, 36 by 8 by 4½ feet, and by pushing out the hot coke and quenching on the outside of the oven. Mr. Fulton, however, justly insists that no application of temperature or pressure should be used, which would tend to bring about the undesirable dense structure of, for instance, natural coke. If rapid heat is required, oblong ovens with or without flues, may be readily adopted without deepening of the coal charges to produce undesirable density of coke.

Mr. W. F. Durfee read a paper giving a minute description of a chemical laboratory erected in 1863, as an adjunct to the experimental steel-works at Wyandotte. He gave a sketch of the line of investigation followed out, and the often ludicrous opinions and statements advanced to hinder work at "Durfee's apothecary shop."

Professor Dr. Persifor Frazer followed with Notes on the Serpentine Belt of Chester County, Pennsylvania, and Supplementary Remarks on the Rocks of South Wales. Mr. F. W. Gordon, of Messrs. Witherow & Gordon, Pittsburg, Pa., in a paper entitled Boilers and Boiler-Setting for Blast-Furnaces, explained with the aid of diagrams the latest methods of boiler-setting introduced by them in their work, the principal feature of the design being the arrangement for conducting gas and air into the combustion-chamber. Messrs. Barnes, Durfee, and Birkinbine spoke on the subject, the discussion drifting into the causes of boiler explosions at blast-furnaces as influenced by the boiler setting.

Mr. F. P. Dewey, of Washington, gave the results of his observations on a tour of inspection in Canadian iron mines, which elicited no discussion.

The last paper brought before the meeting was that of J. H. Clemes, of Sonora, Mexico, Notes on an Experimental Working of Silver Ores by the Leaching Process, to which we shall refer at greater length in a future issue. The results were subjected to a critical review by Mr. C. A. Stetefeldt, who expressed doubts as to the accuracy of the analysis of the ore given, and who gave a very instructive summary of his experience and that of Mr. C. A. Russell, of the Ontario mill, on many points involved. Professor Egleston, too, spoke at length, dwelling particularly on the necessity of leaching with an ascending current and on the danger of using too much salt in chlorination.

A letter by Mr. Bridgeman was submitted, calling attention to the wish expressed by Bergrath von Groddeck, of the Clausthal School, to collect typical specimens of the ores, country-rock, etc., of the American mines, with a view to aiding him in his researches on ore-deposits. The communication was favorably received, and will, we trust, lead to numerous responses.

After the reading of a number of papers by title, and the passing of resolutions acknowledging courtesies on the part of local members and firms, the meeting adjourned.

In the evening, 125 members, their ladies, and their Trojan friends, sat down to the subscription-dinner, which passed off pleasantly.

THE EXCURSION TO THE HUDSON RIVER ORE-BANKS.

On Friday morning, a special train took the members to Burden station, on the Hudson River Railroad, between Livingston and Catskill stations, to examine the property of the Hudson Ore and Iron Company, of which James A. Burden is president, and to whom the credit of having detected the value of the deposits is due. The discovery of the principal vein is due to a systematically organized search for ores throughout the entire Hudson River valley. The ore of the principal of the two veins, the Dickson, escaped the attention of those working in the vicinity a few years ago, as it is a carbonate, and resembles more a limestone than an iron ore. The party was first conducted to the roasting-kilns, of which three are now building in a small ravine. These kilns, very substantially built, have a hight of 60 feet, and an inside diameter of 21 feet, contracting from a point 22 feet 9½ inches above the ground level to 15 feet 6 inches at the discharge, 10 feet 3 inches above the level. The shaft rests on six cast-iron pillars, there being a discharge-slide between each pair of pillars. A central discharge-cone projects into the kiln in the usual manner. This unusual hight of the kiln was chosen because experience with experimental kilns, 15 and 30 feet high, at the mines proper, showed that the ore has a tendency to clinker or "loop," which interferes with the expulsion of the sulphur. It is believed that the additional hight will destroy all tendency to looping. The kilns—of which three are nearly finished, and to which two more are to be added, the total contemplated plant being ten kilns—will be charged directly from the drop-bottom mine cars, which will be run over their tops on a track. The fuel to be used will be anthracite culm, the total quantity used being two per cent. The ore is drawn directly, in a hot condition, from the discharged chutes, and is weighed, so that the sales of ore are made on the basis of dry material. The kilns are rated at a capacity of 200 tons a day. The main object, of course, is to expel the carbonic acid, but they will at the same time perform the important office of reducing the quantity of sulphur in the raw ore.

After the visit to the kilns, the party partook of a luncheon served on the train, and then boarded a train on the narrow-gauge railroad leading to the mines, to the village of Burden, where a considerable number of workingmen's houses have been put up. The party first ascended a knoll through which the Cannon, the lower vein, passes, and on which are the openings of a party of Pottsville capitalists now abandoned. From this knoll, the course of the upper, the Dickson vein, could be traced by a number of shallow openings on it. Altogether, the vein has been followed for a distance of fully five miles. The principal work has been done at one point, where a shaft has been sunk three hundred feet deep, and headings have been driven. The Dickson vein at this point has a total thickness of 24 feet of ore, the firm hanging-wall being siliceous, while the foot-wall is shale. It does not appear likely that with ample pillars much timbering will be needed. The bed dips one in three. The mining work is laid out in the manner customary in the anthracite regions, the slope having a double track, upon which trains of cars will be hoisted. Only one rope is used, for what reason is not apparent. There is a Rand duplex compressor, with a plant of 16 drills, the mining being done by contract, we understand, for 40 cents a ton. There are at the slope three kilns, two 15 feet high and one 30 feet high, the cars being lifted to their top level by an elevator. These are merely experimental, and a considerable quantity of the ore is now being stocked on a dump for delivery to the new plant of kilns. A large quantity of washed ore is piled up under the kilns. It exhibits, however, the defects of irregular roasting, so that, we presume, the roasted ore prepared in these kilns contains more sulphur than it will when the permanent kiln plant is brought into use.

Much of the ore is so close a mixture of the minerals of which it is an aggregate that it is difficult to trace its mineralogical composition. Some of it, however, coarse in grain, shows spathic iron, calcspar, seams of iron pyrites, and occasionally gypsum. Analyses of the roasted ore show the following composition:

Roasted Ore from Hudson River Ore and Iron Company's Mines.

Metallic iron	51·520	50·080	52·05	51·09	51·880	51·160	50·820	51·296	52·580
Silica	8·760	8·970	8·08	9·14	8·860	9·200	9·030		8·110
Phosphorus	0·024	0·029		0·03	0·034	0·029	0·031	0·027	0·033
Sulphur	0·657	0·730		0·72	0·682	0·350	0·600	0·672	0·530
Lime	4·560		3·22						
Magnesia	7·390		6·81						
Alumina	1·270		2·60						
Oxide of manganese	3·190								

The ore, it will be seen, runs very uniformly in iron and silica. Magnesia seems to predominate over lime, while the phosphorus is always low, coming below the specifications for Bessemer pig. The sulphur, with one exception, goes above one half of one per cent, and will require careful attention to the character of the fuel and pretty high heats to bring within the requirements of steel producers. We presume that the samples analyzed do not represent the results attainable with better roasting facilities, a fact which is indicated by the low figure in one of the analyses. How far an increase in the percentage of pyrites in the ore mixture at greater depth will affect its quality remains to be seen. The depth reached, 300 feet, is presumably below drainage level, or near it, so that probably the maximum has been attained. Careful roasting will cope with it. The ore roasted is porous and easily reduced. The use of Hudson River ore at Crown Point shows the following result:

BURDEN WHILE WORKING MILL IRON WITH ALL LAKE CHAMPLAIN ORES.

Fuel.	Ore.	Flux.	Daily product.
4400 lbs.	5600@6000 lbs.	60 per cent.	54 tons.
	WORKING ONE EIGHTH HUDSON RIVER.		
4400 "	6200 lbs.	52 per cent.	60 "
	WORKING ONE QUARTER HUDSON RIVER.		
4400 "	6280 lbs.	44 per cent.	64 "

These figures illustrate the advantages of an ore approaching hematite over the dense and siliceous magnetites of Lake Champlain. The Hudson River Ore and Iron Company has its plans for a total output of 2000 tons of ore per day, and its policy is understood to be to market it at a low figure, in order to compensate for the high cost of fuel in the East. The shipping facilities by water on the Hudson River and by rail over the Hudson River Railroad are exceptionally good, and chutes and docks are now building to utilize the natural advantages. It is stated that, in all, the company will have expended upward of $500,000 before the improvements now making are completed.

AMONG THE IRON-WORKERS.—LEBANON.

EDITOR ENGINEERING AND MINING JOURNAL:

SIR: One can go but a short distance in Pennsylvania, without hearing repeatedly of her great coal and iron interests; on all sides, if he goes to her industrial centers, does he hear the prospects discussed. The Doctor and I were much interested in blast-furnaces and other components of the iron plant, and determined to see the actual operations as they are carried on throughout the State. Winter is not the best time to study the resources of a country, and particularly if one wants to see mining and smelting going on; but as it was the only time at our disposal, we determined to make the best of it, and start out in spite of the January weather. On the morning of our departure, the heavens looked decidedly gray and snowy, and a slight sleet was falling. However, we concluded not to wait, fearing lest the whole month should bring no more cheerful prospect.

The Philadelphia & Reading Railroad, as it winds along the Schuylkill, soon carries one into the heart of the eastern iron country. The road hardly leaves the city where so many industries find their market, before it is in the midst of the busy producers. From Phœnixville onward, accumulating signs bear witness to the great importance of these staple industries. At the time of our visit, all lay beneath a broad mantle of snow, broken only by the dark chimneys and furnace-stacks of some factory or iron-works. The cars, as if in contrast with the disagreeable exterior, were excessively warm, and the Doctor and I were for a time in much greater danger of roasting than of freezing. The driving sleet and steam-coated windows shut us off from the outside world; the isolation made the passengers communicative, and it was but a short time before we found out the destination and partial biography of most of our neighbors. The delicate-looking lady, wrapped up in furs and shawls, was bound for the Sanitarium at Wernersville, while the hearty, prosperous-looking man at her side was off for a visit to his furnaces—in these days of iron depression, we should perhaps say, the *apparently* prosperous; and so it was throughout the crowd, each in pursuit of some object, unmindful of storm and discomfort. A ride of a little over three hours brought us to Lebanon, and here we made our first stop.

Lebanon had always been synonymous in our minds with Weimer, so our first inquiry was for his works. The station-master gave us the necessary directions and politely took charge of our hand-satchels until we should determine on a hotel. The Doctor was anxious lest we should not get them back again when we wanted, so he questioned the agent as to how long the office kept open. The man smiled, as he replied: "We're open all the time, save a few hours on Sunday." The Doctor and I were quite surprised at such activity; for we expected to find rather primitive arrangements as soon as we left the metropolis. The Weimer Machine-Works were fortunately quite near the station, so that we had to take but a few steps to reach them. The offices and drawing-rooms are located in a comfortable and pleasing building recently

Digitized by Google

erected; while the works proper, the machine-shops, casting-rooms, etc., give some indications of the extensive business carried on by the firm. Blowing-engines constitute the chief product of the works, although all articles of blast-furnace mechanism are included in the list. Engines of various sizes, and in all stages of manufacture, naturally formed the most conspicuous objects in the workshops. One huge machine destined, I think, for some firm in Alabama, had an air-cylinder of seven feet: it would seem an efficient aid in helping a furnace digest even such a hard diet as magnetite and limestone. In another part of the works, large iron pipes for the hot-air stoves were casting. The molder's art seemed most wonderful to the uninitiated. Molds of large size and difficult pattern were so nicely wrought that the molten metal could not but confine itself to their limits. Great ovens, large enough, but far too heated for human habitation, were accessible from the casting-rooms, so that the molds might be properly dried before being intrusted with the liquid iron. The shops held our attention for some time, but our chief interest centered in the drawing-rooms; for from them issued the elaborate plans necessary for such large undertakings. A commodious, well-lighted room afforded every facility for the draftsmen engaged in working up the details of the furnace mechanisms. Some forty ample drawers accommodated the large collection of tracings and original drawings. Formerly, the drawings were made in pencil on regular drafting paper, and then inked in; tracings on the prepared cloth being then made from these original designs. At present, however, the drawings are only made in pencil, traced on the prepared cloth, and from this tracing the necessary copies got by the popular "blue process." The more recent designs are patterns of elegance in furnace construction; the light and pleasing proportions being in marked contrast with the clumsy masonry of a few years back. The conditions of production which must be considered by the rational designer, and which decide the resulting proportions, are so very numerous that one of these apparently simple designs is the outcome of no little thought. Ore, fuel, flux, blast-pressure, and temperature, etc., all have weight in determining the proper shape of a furnace, and it is only of late years that these important factors have received their proper consideration. The present tendency toward high shafts and lighter construction is fully illustrated by the numerous designs of old stone furnaces which have been enlarged by superstructures of brick and iron. Indeed, a most important branch of the firm's business is in modernizing old furnaces, one design in particular having for its foundation a heavy stone structure fully one hundred years old. As the works were established in 1856, the proprietors have had ample time for experience. One old machine in the shop interested us not a little on account of its history. It was invented in 1857, but was never used to any extent. This present year it will be called into requisition, and is undergoing the necessary preparations. That the head of the firm, Mr. P. L. Weimer, has been most actively employed during his long years of service, is fully shown by the number of patents which have been granted him for his numerous furnace and mechanical inventions. Up to the present time, he enjoys the protection of about one hundred and seventy-five letters patent. Most readers will probably be ignorant of the cost of a furnace plant, and, as an estimate from a reliable source, it may not be uninteresting to record the expense of a small furnace built last year in the neighborhood of Carlisle. Like all the rest of its work, the firm has kept tracings of the designs, and we were pleased to have the opportunity of examining them and of learning the cost. The furnace was built on modern principles, thus saving heavy masonry and castings, and, while more desirable than the olden style, was also less expensive. Though the dimensions were quite modest, being but fifty feet high and eleven feet bosh, yet the furnace, when fed on coke, was capable of a daily output of from forty to fifty tons. The total cost of the work, stack, blowing-engine, pipe-stove, and in fact every thing exclusive of the ground, was a little under $40,000, and we were told that it was one of the cheapest plants ever put up. The iron-work on this plant cost $25,000, but part of the price was paid in the pig-iron produced when the works were in operation, so that the cost would really be somewhat less. Mr. Weimer, when he learned the scientific purpose of our trip, was very attentive, and on our departure gave us copies of some of his most improved designs for furnace plant. We were quite anxious to obtain drawings of the small furnace spoken of, so he kindly offered to have copies made and sent to our address in Philadelphia.

Though we had by no means exhausted the resources of the works, we concluded our visit, and turned our attention to the Colebrook Furnaces, about a mile farther down the railroad. Our most direct path lay in the beaten track made by the workmen on the snow-covered sleepers. The flagman told us that, as we would meet any train that might be coming along just then, we were in no danger on that score. I had never quite understood how so many accidents occur to people walking on the track; but it became a little clearer to me a few minutes later, when a glaring head-light suddenly loomed up before us, and we had to hurriedly spring aside into the snow. The day was nearly spent when we reached the furnaces, so that our view was more general and impressive than detailed and strictly scientific. The Colebrook are considered the most modern furnaces in the neighborhood; but they have the misfortune, we are told, to be the result of ideas indiscriminately collected, rather than growing out of any systematic design. The plant at these works has been fearfully expensive, the two furnaces alone costing some $800,000. When to this is added the additional cost of Whitwell stoves, engines, dressed-stone casting-houses, and other such expensive incidentals, we have an aggregate of capital which can ill afford to be idle when the financial barometer shows depression. A deepening twilight warned us that strangers who walk on busy tracks had better get hotel-ward; so, after only a hasty glance, we turned back again toward the town. The men were drawing cinder off from the furnace; and as we glanced back at the works, its ruddy reflection spread over every thing. The dull, monotonous gray tints were changed to bright rosy ones, and the effect recalled to our minds the Plutonists and their fiery hypothesis of the world-formation. The sulphurous fumes and odor of overheated iron seemed to cling to us and fill our nostrils during the entire night. Nor were our nerves particularly prepared for sleepfulness, when the room clerk informed us, after assigning our persons to the third floor, that there were three avenues of escape, should we be overtaken by that recent nightmare of the modern traveler—fire.

CARL.

THE MANUFACTURE OF BLUESTONE AT THE LYON MILL, DAYTON, NEVADA.*

By J. E. Gignoux.

The origin of the bluestone industry at Dayton, Nevada, which subsequently attained such magnitude, was due to the endeavors of certain mill-owners, who found it necessary to refine, in order to profitably dispose of the bullion which they obtained in working Comstock tailings. By the base process, as the one in vogue was termed, it was found advisable to employ large quantities of copper sulphate in amalgamating, and even as much as 20 pounds to a ton of tailings were used. In consequence, the bullion produced contained from 80 to 90 per cent of base metal, principally copper. Besides the loss in copper, the mill-owner was obliged to bear a heavy discount on his produce.

The first crude attempts at refining were made by the Lyon Mill and Mining Company, and were in imitation of the sulphuric acid process practiced at the mints. The bullion proved to be too base for its success, owing to the great length of time required to dissolve in acid, and it is also stated that a significant mechanical loss of the precious metals was found to be unavoidable.

Subsequently, the bullion was subjected to a sulphurizing process, which consisted in placing in iron kettles charges of about 400 pounds of metal with 20 per cent of sulphur. Layers were made by placing barrel-staves alternately with the charge. The kettles were provided with cast-iron covers having flanges corresponding with similar flanges and bolt-holes on the kettles. When charged, the cover was luted and tightly bolted to the kettle, when a gentle heat was applied for about nine hours. On becoming cool, that portion of the metal converted into sulphide was removed, the remainder received new sulphur, and the process continued until all the metal was converted, for which about 40 per cent of the original weight in sulphur was found necessary. The sulphurized material was next crushed in a Chili mill, passed through a No. 10 sieve, and sent to the furnace-house, where it underwent a desulphurizing roasting. This was performed in a small reverberatory furnace, which was charged with 400 pounds of the granulations. A complete desulphurization was effected in about ten hours, or until the whole was thoroughly heated to a bright red by a very gradually increasing fire. The charge, when drawn, was again crushed and passed through a No. 20 sieve, when it was again roasted in the same furnace, and converted into an oxide. Wood as free from pitch as possible was used, and air was admitted through the bridge-wall. This roasting occupied about twelve hours, and required constant stirring. Leaching was then resorted to, and carried out in almost the identical manner to be subsequently described.

The method in use at the present time is based upon the partial separation which takes place in the retorts when great precaution is used to avoid melting or overheating the amalgam, and the bullion obtained is in such a porous condition as to allow of its being "brittleized," pulverized, and roasted. Two classes, designated as white and base metal, were obtained. The white metal, as its name implies, is of white appearance, and is formed next to the iron of the retort, and is of much denser structure than the base, acting as a coating or shell around the latter. It consists of about 80 per cent of silver, 15 per cent of copper, and the remaining 5 per cent of iron, lead, antimony, with a little gold. The base metal is reddish-brown in color and spongelike in appearance, forms in the center of the retort, and consists of about 90 per cent of copper and iron, and 10 per cent of silver, gold, and other metals, nearly all the gold contained in the amalgam going with the base. In quantity, the base metal greatly exceeds the white. Formerly, these products were treated separately in refining, although the process was identical except as to the quantity used in the charges. The white metal being less bulky, and having less copper to be oxidized, was treated in larger quantities. In roasting, 400 pounds of base and 500 pounds of white metal were usual charges, and in the dissolving-tubs 1000 pounds composed a charge for base, and from 1200 to 1500 pounds for white metal.

The retorting is carried on for twelve hours. During the first four, a low temperature is maintained, but is gradually increased until the quicksilver begins to distill, when the heat is increased until the operation is terminated. Occasionally, a small loss of quicksilver is experienced on account of imperfect retorting. This item is, however, insignificant when compared with the saving made by this manner of retorting when the expense of the sulphurizing process is considered. The retorts used are cylindrical, and hold 1700 pounds of strained amalgam when a little more than half filled.

At the Dayton Works, the sulphuric acid parting process was introduced, and thereafter no distinction, as previously, between white and base metals was made. All the bullion as it comes from the retorts is broken with a sledge-hammer into pieces about the size of an egg, and thrown into the roasting-furnace after the roasting charge has been withdrawn, and remains over night on the still heated hearth, no more fuel being necessary. From 2000 to 3000 pounds are charged in this manner. In the morning, it is drawn, when it presents a dark gray to black color, and has become quite brittle. It is then crushed in a Chili mill, and is sifted by hand through a No. 20 sieve. One Chinaman does the work. The power for the mill is supplied by the main shaft of the pan-mill, and is inconsiderable.

The pulverized metal is then returned to the roasting-furnace, when it is weighed, and an increase of weight of about one tenth of one per cent is usually found, due to the wearing of the wheel and pan of the Chili mill.

The roasting-furnace is a small reverberatory, the hearth of which is 6 by 10 feet, with the corners filled, giving an oval shape. The arch is low. There are two working-doors, one front and one back, situated about the middle of the furnace. The hearth is laid with Scotch fire-brick set on end. A charge of 500 pounds of the metal is placed in the center of the furnace and spread out until about 3 inches deep. It is kept constantly stirred with an iron paddle of ¾-inch iron, 5 by 12 inches, attached to a handle of wrought-iron pipe 12 feet long, and terminating in a ring. When the charge has attained a dull-red heat, the workman throws over

*From advance-sheets of *The Mineral Resources of the United States*, published by the United States Geological Survey Department of Industrial Statistics. Albert Williams, Jr., Chief of Department.

that portion farthest from the fire to bring it next to the bridge-wall, and then moves all the charge back by slicing it with his paddle, and exposing a new surface to the heat. If the entire charge has become a bright red, care being taken to avoid a greater heat, it is kept in that condition for one hour before drawing. It is then spread out in an iron box 3 by 6 feet, and allowed to cool. When cold, it is carried to the bluestone works in charges of 1000 pounds, first being sifted, and any lumps that have formed being crushed. A gain in oxygen amounting in weight to about 5 per cent of the original charge occurs during roasting. It takes about ten hours to complete the operation, one man doing the work, and requiring about a quarter of a cord of wood.

Circular tubs, 7 feet in diameter and 4 feet deep, are used for leaching or dissolving the copper. They are made with staves cut from 3 by 4-inch joist, and bound together with two iron hoops 3 inches wide made of half-inch iron. The sides are vertical, and the bottoms are let into the sides. The lining is of 6-pound lead, except at the bottoms, and a strip one foot wide on the sides next to the bottoms, which consist of 14-pound lead. They are likewise provided with heavy false bottoms. Steam is admitted through an AA lead pipe, the lower end of which is closed, but has four holes bored in it about one inch from the end. Were the steam allowed to pass directly down through the pipe, it would soften and wear holes through the lead bottoms. The upper ends of the pipes are soldered on the iron steam-pipes, which are provided with valves for the convenience of the operator. The pipe system is suspended from the roof of the operating-room. Each tub is likewise provided with a cold-water pipe.

A bath consisting of 2½ pounds of 45 degrees Baumé sulphuric acid for each pound of copper contained in the charge is prepared by reducing the strength with water to 20 degrees Baumé, and is steamed until brought to boiling. The charge is then fed with a small scoop, and scattered over the surface of the bath, continual stirring being kept up with wooden paddles 9 feet long and having blades 4 inches wide. The strength of the solution is kept as near 40 degrees Baumé as practicable by occasionally weakening it. Usually, it takes two hours to feed the charge, but stirring and boiling are continued for four hours. At the end of that time, the bullion should present a white or light-gray appearance, which is dependent upon the success of the previous roasting, and it should be 900 fine or over. The dissolving-tubes are covered with boards and sacking, the steam is turned off, and the charge allowed to settle for four hours.

At times, a small quantity of silver is dissolved, and, in order to save it, the solution is drawn into precipitating-vats in which copper slabs have been laid, and the silver is thrown down as fine metal. The vats are circular, 10 feet in diameter, and provided with steam-pipes, the same style as those used for dissolving-tubs. They are lined with 6-pound lead on the sides, and 10-pound lead on the bottom, no false bottoms being necessary. The floor upon which they rest is lower than the floor of the dissolving-tubs, so as to admit of the liquor being drawn over with a siphon. After the solution has remained in contact with the copper slabs for several hours, tests are made with a salt solution, to determine the presence of silver, and when no further chloride precipitate is visible, the charge is boiled for an hour, and is then allowed to settle for two or three hours before being drawn into the crystallizers.

The bullion remaining in the dissolving-tubs is leached several times, first with acid, and then with water, being stirred and boiled each time. The first leachings go with the charge in the precipitating-vats, the subsequent ones to the weak-liquor tanks for concentration. The metal is placed in the filters, which are lead-lined barrels, provided with perforated wooden false bottoms covered with muslin, and with discharge-pipes let in below the false bottoms. Clean hot water is run over the metal until no more acid reaction is detected with litmus paper at the outlet pipe. All the water from the filters is collected in a tank, as a small quantity of silver is sometimes carried through. Drying the metal in iron pans heated to redness is next resorted to. The silver is then weighed and charged in the parting-kettles, the mint process being adopted, excepting that the gold is not again treated with acid, but is melted when about 700 fine. There being so little of the latter, it was found more economical to pay refining charges. Having the metal in a granulated state very much facilitates the dissolving in strong acid. A charge of 3000 ounces is dissolved in five hours' time with an armful of wood. The silver usually runs from 997 to 999 fine after melting.

What is termed the bluestone cellar at Dayton contains 40 crystallizers, arranged 20 on a side, with draining-tables built along the center of the room. In the floor, above the middle of the cellar, a large tank is sunk, in which is collected the liquor drawn from the crystallizers, after crystallization, and which is called the pump-tank. A leaden trough runs along under the draining-tables, and is connected with this tank, into which the crystallizers are first drained with a short rubber hose. The crystallizers are 7 feet long and 3½ feet wide on the top, and 7 feet long and 3 feet wide at the bottom. The bottoms and ends are lined with 8-pound lead, the sides with 6-pound. Altogether, 473½ pounds of lead are required for each tank. The wood-work is constructed of 2-inch planks, the ends projecting so as to receive half-inch round iron bolts, two on each end, to hold the sides together. No lead strips are used, it having been found more advantageous to allow the crystals of bluestone to form on the bottoms and sides of the crystallizers, from which they can readily be removed in large cakes requiring to be simply loosened with a bar-chisel. Boards and sacking are used to cover the crystallizers when the liquor is first introduced, and remain on for three of the five days allowed for the crystals to form. Keeping the liquor warm facilitates the crystallization. At the end of the fifth day, the strength of the liquor is found to be reduced to 28 degrees or 30 degrees Baumé. The bottoms are first loosened and taken out, then the sides, the bluestone laid on the draining-tables and broken up with a wooden mallet. After remaining from twenty-four to forty-eight hours on the tables, it is packed in barrels and stored.

Bluestone made in the above manner is of the best quality and compares favorably with Eastern and imported. It usually commands half a cent a pound higher price than that which is manufactured from copper ore. Each crystallizer yields from 700 to 800 pounds of good crystals, and about 100 pounds of broken and fine material taken out as slush, which is placed on separate tables arranged with a draining-tank, and when dry is set aside to be redissolved as refuse. About 3500 pounds make a refuse charge, and with the water necessary fill two crystallizers, and make first-grade bluestone.

The actual cost of producing bluestone from bullion is difficult to arrive at, owing to the copper having no definite value, and having already served a purpose in the amalgamation. Six cents a pound was paid for the copper contained in base bullion produced by other mills, and no charges for refining were made when under 600 fine in silver. This was found profitable when bluestone could be disposed of at 8 cents a pound. The cost of refining is about 2½ cents a pound for bluestone produced.

All the tailing-mills in the vicinity copied at least portions of the process in use at the Lyon mill. At the Atlanta mill, pains are taken to closely separate the base from the white metal when it comes from the retorts, the former only being refined, the latter melted and sold as 800 fine bullion. Besides the refining charges, they sustain a loss of 20 per cent of copper, less the actual cost of refining themselves. This loss is in some measure unavoidable at small mills, as they can not afford to allow their bullion to accumulate to such quantities as would insure economical refining.

At the Omega mill, there is a large refinery for treating all the base bullion produced at the mills controlled by the Pacific Milling Company. Each mill is provided with a Wiegand digester, which is an ingenious adaptation to this purpose of an old German method of separating lead from silver amalgam. The late Mr. C. Wiegand succeeded in parting the silver from the copper and gold by leaching the raw amalgam with heated quicksilver. While the silver is carried out of the digester, the base amalgam remains. Amalgam treated by his method, after straining, retorting, and melting, gives bullion 900 fine in silver. The difficulty experienced in heating the quicksilver, the loss through imperfect pipe-joints, that is sustained in handling such large quantities, also the cost of manipulation, all tend to make the process expensive; besides which, the copper still contained in the bullion, amounting to 10 per cent, is lost to the mills. The base bullion is refined in the manner described, and the bluestone made returned to the mills.

The facilities of the Dayton Works for refining bullion and manufacturing bluestone were greatly augmented by the erection of sulphuric acid chambers. The acid is made from sulphur mined in Humboldt County, Nevada, and is produced at an expense of about $20 a ton. The chambers have a capacity of about 2½ tons a day of 45 degrees Baumé. Concentrators are employed for producing 62 degrees Baumé acid for transportation and supplying the Carson Mint.

The demand for bluestone being much in excess of what could be made from the refining of base bullion, large quantities of it were manufactured from copper ore and cement copper. The prices at which the ore was purchased ranged from $2.25 a unit for 20 per cent, to $3.25 for 40 per cent, increasing 25 cents a unit for every 5 per cent increase in assay for the copper ore delivered at Dayton. A charge of $10 a ton is made for ores which require roasting.

The Walker River mines in Esmeralda County, Nevada, furnished most of the ore, which consisted principally of chrysocolla, azurite, malachite, cuprite, chalcocite, chalcopyrite, tetrahedrite, and chalcanthite in considerable quantities from the Bluestone mine. The cement copper came from Wheatland in California. The advantages which the miners derived from shipping rich ores which did not require to be roasted led them into the habit of assorting very closely, and reserving sulphuret and low-grade material for reduction at some future period, when the facilities for transportation shall have increased. In consequence, high grades of carbonates and silicates formed the bulk of the ore received at Dayton.

The copper roasting-furnace in use is a one-floor reverberatory, 30 feet long and 10 feet wide, with three working hearths and six doors, three of which are on a side. The fire-room is 17 inches. A low arch and perforated bridge-wall, the apertures communicating with the air, are used. The chimney employed for a direct draught is 30 feet high; but when the ore-drier is in use, the smoke is made to traverse a distance of 90 feet under drying-plates, and is then led off through a higher stack. Ore is fed through a hopper, and is discharged into small iron cars. One man working on a pass of eight hours performs the labor, fuel and ore being brought to him. A charge usually consists of 800 pounds, which is shifted every four hours. It is allowed to remain in the furnace twelve hours, thus making the capacity 4800 pounds a day. A little over three quarters of a cord of wood are consumed in twenty-four hours. Enough sulphur is present in the ore to ignite and burn on the first hearth, the charge requiring occasional stirring. On the second hearth, it is heated dull red all through, and does not need much stirring unless a disposition to cake is manifested. When the ore reaches the third hearth, the one nearest the fire-bridge, it requires more stirring and frequent removing back from the fire, as the heat is sufficient to melt the charge. A steady bright-red heat is maintained during the four hours it remains there. About twenty minutes' time is consumed in discharging, shifting the two other charges, and again charging the furnace. The cost of roasting is estimated at $7.50 a ton.

Ores which do not require roasting, and also those which have been so treated, are carried to the bluestone works, or to the mill solution tank, where they are used in making bluestone solution, which serves as an economical substitute for dry bluestone.

At the mill tower, acid is used for the bath, and many residues from the bluestone which do not contain much copper are also utilized. The solution is run into the amalgamating-pans from tanks where it has been reduced in strength to 20 degrees Baumé. The estimated cost of this solution is equivalent to 4 cents a pound for bluestone crystals, making an important saving where such qualities of low-grade tailings are worked.

The ore at the bluestone works is treated in dissolving-tubs similar to those used in refining bullion, acid being added in the bath in excess of 2½ pounds to the pound of copper contained, according to the nature of the ore. The absence or presence of lime or iron is taken into consideration. Sulphate of iron and gypsum, when these substances are present, crystallize with the sulphate of copper, deteriorating the quality of the bluestone, which is then of the second grade. As this grade is sold at lower prices than the first grade, and also because of a prejudice existing among some mill-men that better results in silver are obtained from the use of impure bluestone for pan amalgamation, a more ready sale exists for it than for the purer article. Owing to the impurities mentioned, a

Digitized by Google

much larger product is obtained than could theoretically be made from the copper contained in the ore.

The charges vary from 1300 to 1800 pounds, and the solution is made from 37 degrees to 40 degrees Baumé strong. Eight hours is the time usually occupied to make and settle a charge. It is drawn directly into the crystallizing-tanks in the cellar by means of a four-ply rubber hose, which is attached to a float in the tub to prevent disturbing the sediment at the bottom. A glass tube is inserted in the solution from time to time, and by closing the end before withdrawing it the quantity of clear liquor above the sediment is observed. The utmost precaution is necessary to prevent drawing the sediment into the crystallizers. About the same time is allowed for crystallization of ore solution as for bullion. A better grade of bluestone is generally produced by drawing off the solution sooner, as the sulphates of iron and lime form crystals on the top of those of sulphate of copper.

All the liquor from the crystallizing-tanks is drawn into the pump-tank, whence it is pumped by means of a steam-injector, made of lead, into high tanks on the upper floor, and from them fed into the condensing-pans. These consist of two leaden pans, one of which is set 8 inches higher than the other. The larger pan rests partly on iron plates, which are so arranged as to protect the lead from too great a heat. They are made of 16-pound lead, 6 feet wide; one 10 feet, the other 8 feet long. The sides are 12 inches high, and are surrounded by masonwork. The flues are built parallel with the greatest dimension of the pans, and the heat is made to traverse their entire length three times before escaping into a chimney 40 feet high. The fire-room is 20 inches. At the beginning of the concentrating operation, both pans are filled from the high tanks, and a continuous stream, equivalent to the loss by evaporation, is run into the higher pan and siphoned from it into the lower pan. It is kept at a quiet boiling temperature until the strength of the charge in the larger pan has been raised to 41 degrees Baumé: that from the smaller pan decreasing the strength to 39 degrees Baumé as it is drawn into the crystallizers in the cellar. A long four-ply rubber hose is used for the purpose. Two crystallizers hold the condensed charge and yield from 400 to 600 pounds of inferior bluestone, according to the quality of the solution used. Clear liquor from the settling-tanks, into which the residues from the dissolving-tubs have been washed, is likewise pumped into the high tanks and concentrated. Two charges can be condensed in the pans during twenty-four hours, with the consumption of one cord of wood. The boiler-man also attends to this fire. About one cent a pound for the bluestone produced was estimated as the cost of concentrating.

All washings containing copper in solution the strength of which is below 15 degrees Baumé are weakened to 5 degrees, and are then run into the iron tanks, in which the copper is thrown down. Old crystallizing tanks are used for the purpose. They are so arranged that the overflow from one passes into the another, until the liquor is free from copper. A false bottom is made in them of wooden paddles which are worn too short for further use in the dissolving-tubs, and about 300 pounds of scrap wrought-iron are laid upon it. When the precipitated copper covers the iron, it is washed down into the bottom of the tank and then allowed to accumulate. When removed, it is spread upon a wooden platform and sun-dried. It is then screened, and that portion which does not pass through a 20-mesh sieve is melted into bars and used in the refinery for throwing down silver. The finer portion goes to the roasting-furnace, to be subjected to an oxidizing roasting and used again in the manufacture of bluestone.

Not an unimportant factor in the product of the Dayton Works is the copper obtained from the United States Mint at Carson. This institution purchases the acid used in the refinery, and partly pays for it with copper solution. As the mint solution carries a great excess of acid, it has to be used in conjunction with cement copper, or rich ore, and is substituted for new acid in the dissolving-tub baths.

The cost of manufacturing bluestone from ore at the Dayton Works was estimated at 6 cents a pound when 20 per cent ore could be purchased at $2.25. The average cost of labor was $3 a day, chamber acid costing $20 a ton and wood $6 a cord. The wear of the sheet-lead, which, with freight added, cost about 11 cents a pound, and a lead-burner's wages at $4.50 a day, he having to be employed continuously, also formed an important item in the estimate.

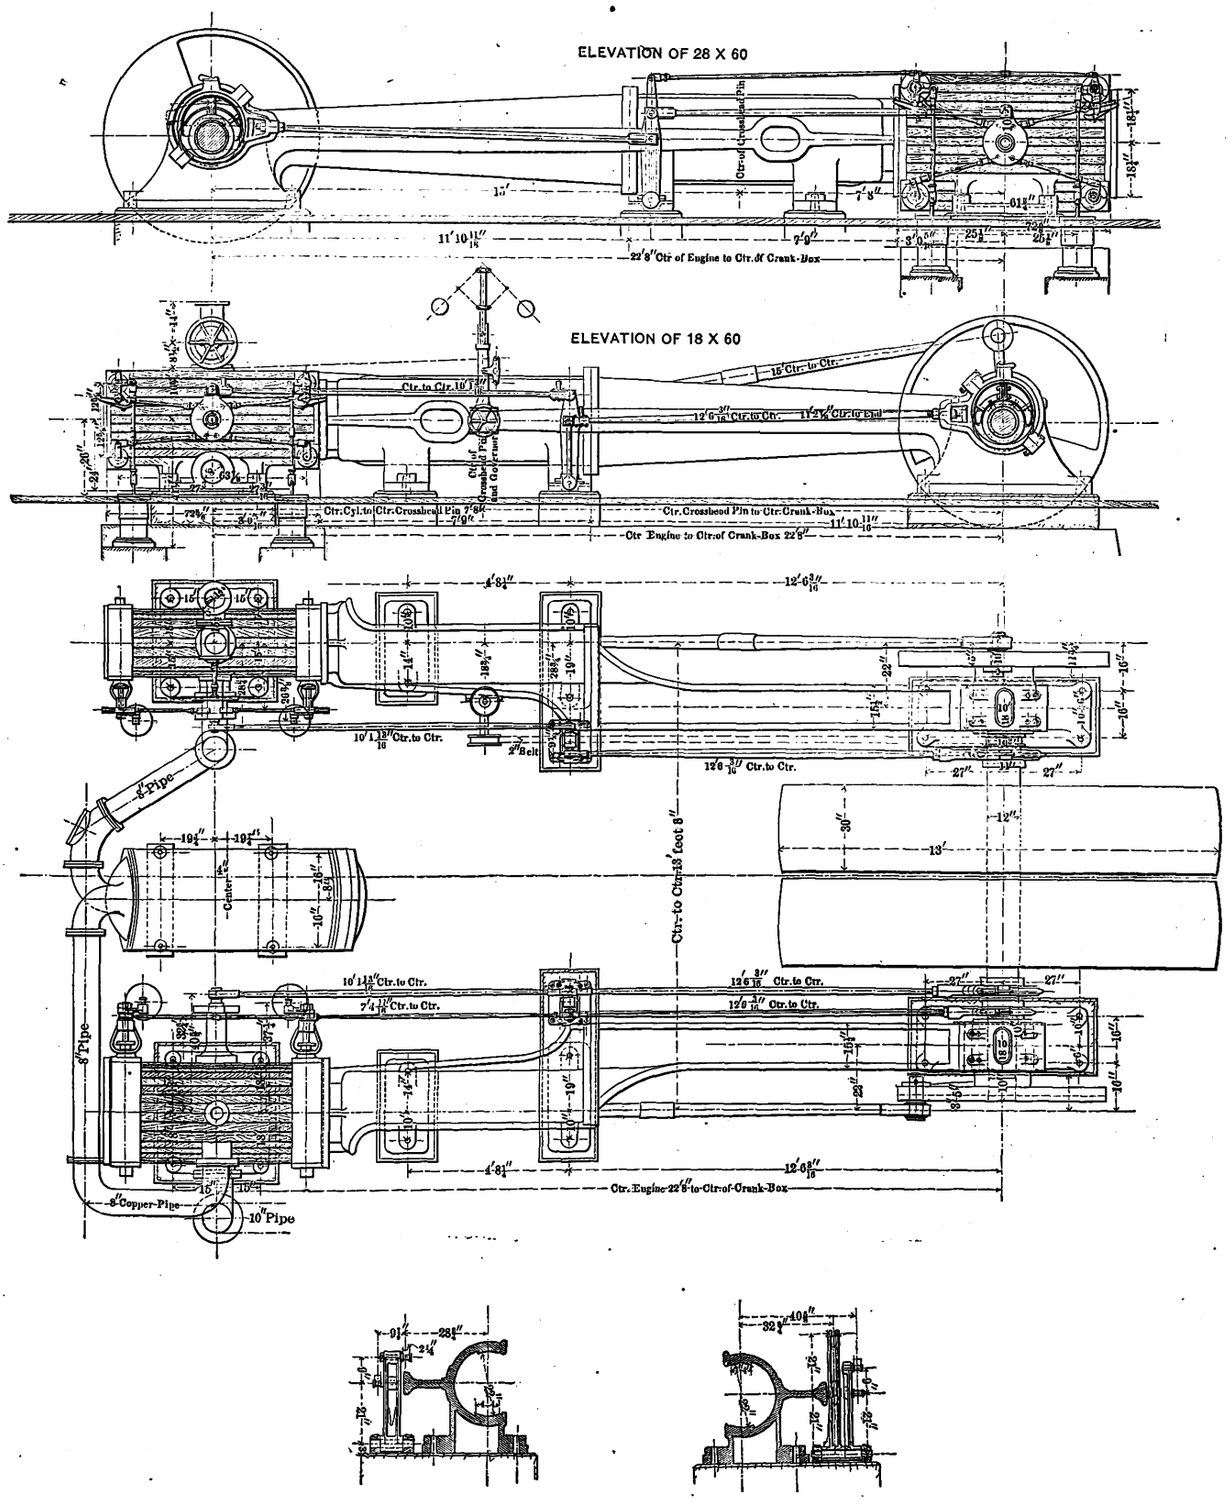
During the years 1879, 1880, 1881, the output averaged about 320 tons a year. Several years previous, a much greater quantity was made and sold, taxing the capacity of the works. Since 1881, there has been a perceptible falling off in the demand, owing to a decrease in the tailings milling industry. Shipping to a foreign market is out of the question, on account of the cost of transportation, which likewise serves to keep foreign manufactured bluestone from coming into competition with that made in Nevada.

THE significance of the small quantity of carbonic acid in the atmosphere was fully appreciated during the first half of this century. Through careful researches, it was ascertained that the carbonic acid produced by the decomposition of organic substances, by respiration, by combustion, etc., is absorbed, through the agency of the sun's rays, in the form of carbon. The question has been suggested whether the enormous quantities of coal annually burned in factories and dwellings might not have some effect upon the atmosphere, gradually increasing the carbonic acid in it. Dr. Clemens Winkler, of Freiberg, has gathered some curious figures on this point, which we believe will put at rest any fears on that score. There are very few, we imagine, who have any idea of the enormous quantity of carbon which exists in the atmosphere in the shape of carbonic acid. Dr. Winkler, from the known weight of the atmosphere and its percentage of carbonic acid, 0·04 per cent of the volume, has figured out that there are not less than 800,000 millions of tons of carbon in the air. The total production of coal in the world is roughly 360 millions of tons, equal to 942 millions of tons of freshly cut pine, or 2625 millions of trees of 80 years' growth in a moderate climate. The total population of the world, about 1200 millions of human beings, annually, in maintaining life, breathes into the air carbonic acid enough to equal 180 millions of tons of coal. And yet the quantities of carbonic acid thus sent into the atmosphere are insignificant as compared with the enormous quantity of 800,000 millions of tons referred to.

A MODERN ENGLISH STEEL PLANT.

The most recent addition to the works in Middlesborough, says *Iron*, is the Northeastern Steel-Works, which were begun in 1881, and the company made its first heat of Bessemer steel on May 31st, 1883. Actual work was begun in double shift in the middle of the following month—June—from which time up to the present, the works have been in constant operation, and the output in each week has exceeded that of the preceding one, the rate of working now being from 1000 to 1200 tons weekly. The works occupy 22 acres of ground, which is in the form of a triangle, lying with its base toward the river—the river itself forming the north boundary. The works were designed by Mr. Arthur Cooper, the manager, who has so arranged them that the work proceeds regularly on, stage by stage, from one end to the other. The various departments are placed under one main roof, which is 1030 feet long by 160 feet wide, the converters being at the northern end, and the cogging and rail-mills and finishing-shop following in proper sequence. The raw materials are brought in to the rear of the basic Bessemer converters (which have Holley's movable shells), and where there are three cupolas for melting the pig-iron. The dolomite for lining the converters is stored in bunkers, and before being used is calcined in the cupolas, of which there are three. The calcined material is crushed under edge-runners, and fed into incorporating-mills, where it is mixed with tar to the consistency of stiff paste, in which condition it is used for lining the converters and making the bottoms. Over the converters is a 60-ton traveling-crane, by which they are lifted bodily from their trunnions and carried to the rear to be lined, where they are arranged under a 30-ton traveler. At present, the pig is melted in cupolas, but it is intended eventually to work on the direct system, taking the molten iron from the adjacent furnaces directly to the converter. The three pig-iron cupolas are arranged so that the raw material is taken up to a hight of 21 feet by means of a 20-ton hydraulic lift, and there charged with the necessary quantity of coke and limestone. When melted, the iron is drawn out on the ground floor into 12-ton ladles, and then pushed forward by means of a small locomotive to another 20-ton lift, by which it is hoisted to the converter stage-level, which is 21 feet above the ground line, also on the same level as the charging stage. It is then pushed forward to the converter by a small locomotive which is in waiting on the converter staging. The ladle is then tipped by means of a worm-and-wheel, and the metal passes through a short spout into the converter. The spiegel cupolas are close by the converters, and lime is shot into the converters from an upper platform. After the metal has been blown, it is teemed into a ladle carried by a transfer-crane. This crane receives from two converters, another similar crane receives from other two converters, there being four 10-ton converters. The ladle carried by the transfer-crane is taken by a center casting-crane, which covers a pit 60 feet in diameter. This crane was specially designed for the plant by Messrs. Head, Wrightson & Co., of Stockton. The ingot molds are removed by four 6-ton cranes arranged around the pit, the ingots being taken thence to the re-heating furnaces in the cogging-mill. Soaking-pits on Mr. Gjers's system have been constructed, and will shortly be started. The converters are blown by a pair of vertical compound condensing engines, the high-pressure cylinder being 40 inches in diameter, and the low-pressure 66 inches, with a stroke of 5 feet. The blowing-cylinders are 54 inches in diameter. There are two pairs of horizontal pumping-engines for the hydraulic work, there being four pumping-cylinders on each engine. The steam-cylinders are 26 inches in diameter, with a 3-foot stroke; the pump-plungers being 6 inches in diameter.

The cogging-mill rolls are 36 inches in diameter and 7 feet 6 inches long. The engines for driving this mill have 40-inch cylinders and a 5-foot stroke, and are geared at 1 to 2. In this mill, slabs 16 inches wide are made; also rail and other blooms. The bloom or slab having been brought down to the required size in the mill, is passed forward by means of live rollers to the bloom-shears, where the crop-ends are cut off, and the bloom itself cut to any requisite length. The blooms, if required for export, are then placed on a skid and moved along to the outside of the mill for inspection; but if they are to be still further manipulated, they are run down by means of live rollers to the rail and finishing-mill, the rolls of which are 28 inches diameter and 7 feet long, and are driven by a pair of 50-inch cylinder-engines with a 54-inch stroke. A train of rollers conducts the billet or rail, as the case may be, either to the billet-shears or the rail-saw. If the rails are making, after being cut to requisite length, they are taken on a skid to the hot bank and allowed to cool. When sufficiently cooled, they are removed by means of two 3-ton steam portable cranes to the cold bank, thence to the straightening machines and rail-drills, and afterward to the benches, where they are inspected and loaded on trucks, which are placed in docks alongside these benches. The company has commodious sidings, connected, of course, with the Northeastern Railroad system. The works afford employment to about 500 hands, and are producing about 1000 tons of rails per week by the basic Bessemer process, Cleveland and cinder pig being exclusively used.



JIGGED COAL.—A circumstance which has had a depressing influence on the smaller sizes of anthracite coal has been the growing quantity of jigged coal offered in the markets, being largely the product of working culm-piles, etc. While the growth of this industry will be hailed with pleasure by all who have been hoping for a reduction in the fearful waste in our anthracite region, the jigged coal unfortunately comes to the market too frequently under false pretenses. Every effort is made to sell it as fresh-mined coal. Some of it undoubtedly is, but some of it is not. Coal obtained from washing a culm-bank, after it has been subject to weathering for years, is undoubtedly a good fuel; but it can not, so far as we are able to judge by inference, claim to be as good as fresh-mined coal. Buyers will therefore do well to be on their guard.

We may here note that, from the accounts which reach us, the jigging operation is carried on in a very crude manner in some of the dressing-works. Sometimes, the jigs are choked with material, coming with a rush from the breaker; and sometimes, the jig is doing comparatively little. The arrangements for the delivery of the refuse and of the washed coal appear to be defective in many instances, and the quantities of water used generally excessive.

THE LEXINGTON MILL ENGINE.

We illustrate in our present number a specimen of modern engines, one of which was built for the Montana & Utah Mining Company, by Messrs. Fraser & Chalmers, Chicago, Ill. This engine serves as motor for the Lexington Mill, Butte, Montana, and is remarkable for its economy as well as its durability and beauty of design. It is a compound condensing engine, and is provided with a reheating receiver. The high-pressure cylinder is 18 inches in diameter and the low-pressure cylinder

COMPOUND CONDENSING CORLISS ENGINE AT THE LEXINGTON MILL, BUTTE, MONTANA.

28 inches, both having a 60-inch stroke. Both cylinders are provided with Corliss valves, and the admission of steam is controlled by the governor at the high-pressure cylinder, while the cut-off for the low-pressure cylinder is adjusted by hand, to adapt the engines to greater variations—for instance, to run a section of the mill only, and divide the work in such case equally between both cylinders. This adjustable cut-off is a novelty in principle and design, and permits cutting off the admission of steam at any point from zero to full-stroke, while the common Corliss cut-off is limited to four tenths of the stroke.

The receiver, placed between the steam-cylinders, is provided with return-flues, for the circulation of live steam from the boilers, to reheat the steam before entering the low-pressure cylinder. The exhaust steam, leaving the low-pressure cylinder, passes through a feed-water heater, similar in design to the re-heater, and then enters the siphon condenser.

No critical tests as to economy in consumption of fuel have been made as yet; but the practical results are surprising to mill-men. The Lexington Mill is a dry-crushing silver mill, consisting of 50 stamps of 950 pounds each, with all conveyers and elevators, two five-stamp salt batteries, 20 pans, 10 settlers, 2 agitators, screens, furnace conveyers, and feeders for two Stetefeldt furnaces, which machinery, with shaftings at usual terms, may be rated at 275 horse-power. Four tubular boilers 54 inches in diameter, 16 feet long, with 758 square feet of heating surface each, were provided; and although the water supply of the mill is not sufficient to use the condenser, two of these boilers only are in operation to furnish steam to run the entire mill, and this with a consumption of 9½ cords of wood per day of twenty-four hours. The Lexington Mill engines are the first striking instances of the introduction of the best steam engineering practice in silver mines. Their success will, we trust, mark the beginning of a new era, in which due attention is given to this important source of economy.

THE OILS OF THE JAMESON COKING PROCESS.

Mr. Watson Smith has apparently examined with care the oils condensed in saving the by-products in coking in the Jameson modification of the bee-hive oven. He reports:

The tar, as it was at first called, is now, I observe, termed "oils," and Jameson states that he obtains from six to fifteen gallons of tar per ton of coal coked. As to this tar, various reports have got abroad. In the *Journal of the Society of Chemical Industry*, it has been represented in one case as consisting merely of paraffines, liquid and solid, and in another, as containing no aromatic compounds applicable to the manufacture of colors. Now, neither of these statements is quite true, although in part so. Though benzine is quite absent in the Jameson tar, yet in admixture with paraffines, both very small quantities of toluene and larger quantities of xylene are present. I have obtained their nitro-products. Now benzine, toluene, and, I believe, xylene, are found in the Scottish shale spirit produced in the works of the Young Paraffine Light Company. This I proved as far back as 1868. But these aromatic hydrocarbons are mixed in the shale spirit with bodies of about the same vapor tension, belonging to the olefiant gas series, and the attempt to convert them into their corresponding nitro-derivatives results in the production of bodies yielding most acrid and pungent fumes, resembling those of acroleine. Besides rendering the operation of nitration intolerable, the arid bodies are not easily removed from the nitro-benzine and its homologues. But in the spirit from the Jameson oils, the bodies present belong to the marsh-gas series mainly, and hence the aromatic hydro-carbons present might be safely nitrated, and the paraffines afterward removed by steam from the crude nitro-product. The unfortunate circumstance is, that there is so little of this benzine series present, and the representative member (benzine) was quite absent from all samples I have yet examined.

Lubricating and Burning-Oils.—The chief bulk of the Jameson tar, having a specific gravity of 0·960, consists of oils boiling between 250 degrees and 350 degrees, from which on cooling no crystalline substance separates. These oils I have tested as regards their burning qualities in lamps, and as regards lubricating value, and I find them of little value for burning, and of but secondary value as lubricants. One singular feature about them is, that they are quite devoid of "blueness" or fluorescence. If these oils find their way into the market, I would give a timely warning to all those who are buyers of vegetable and animal oils, namely, cease to rely solely on the test of "blueness" or fluorescence of the oils you examine, as a proof of the presence in them of mineral oils!

Paraffine.—But a considerable proportion of oils distills over above 350 degrees, namely, from somewhere about 400 degrees to the point at which pitch remains in the retort, and these oils do separate paraffine scale, though not so much as could be desired, and the paraffine wax obtained has a high melting-point, namely, 58 degrees Cent. It is characteristic of the solid paraffine obtained (of course in small quantity) from certain normal coal-tars, especially those obtained from Wigan cannel, that this paraffine possesses a very high melting-point. The highest melting-point of the paraffine wax made by the Scottish shale distillers is about 52 degrees C.

Phenols.—If the crude oils boiling between 200 degrees and 300 degrees C. be treated with caustic soda lye, and the phenols extracted in the usual way, a fairly large proportion of a peculiar series of phenols of increasing boiling-points is obtained in the crude extract, certain of these phenols resembling the constituents of the creosote of wood-tar. A mere trace of carbolic acid was found, but more of the cresols, and by far the largest bulk of the constituents of the crude phenol distills at from 250 degrees to 300 degrees C. The latter fraction, boiling at about 300 degrees, is a resinous substance perfectly soluble in caustic soda, to which it communicates a red color.

Certain of these phenols yield blue and red colors with alkalis, but of no stability or value. These colored alkaline salts remind one of the colored salts of eupittonic acid, the phenol-like acid derived by the oxidation of Reichenbach's wood-tar pittacal.

Neither naphthalene nor anthracene is present even in traces in Jameson's coke-oven tar. The fact that the specific gravity of this tar is less than that of water is a circumstance sufficient of itself to indicate that it belongs to the class of tars obtained by the distillation of coal at lower temperatures. I think that Jameson's coke-oven tar offers a fine field of research to the scientific chemist, and that his labors *may* develop valuable fruit in a commercial sense, as well as for science; but I do not consider this tar at present, looking at its heterogeneous and unsatisfactory nature, a very inviting subject for present commercial speculation, in view of the possibility of getting the far more valuable real coal-tar as a coke-oven by-product, with its color-yielding and purely aromatic consitutents.
